An origina and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to advertisements; copies only hould be forwarded.

Advertisements (to insure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 35, Rue Franklin, Asnieres, Paris.

# The Hunterian Lecture

ON

# THE ASSOCIATION OF DISEASE OF THE MOUTH WITH RHEUMATOID ARTHRITIS AND CERTAIN OTHER FORMS OF RHEUMATISM.

*Delivered at the Royal College of Surgeons of England on March 6th, 1911.*

BY KENNETH W. GOADBY, D.P.H. CAMB., M.R.C.S.ENG., L.R.C.P.LOND., L.D.S. R.C.S.ENG.,

HUNTERIAN PROFESSOR, ROYAL COLLEGE OF SURGEONS OF ENGLAND; LECTURER ON BACTERIOLOGY AT THE NATIONAL DENTAL HOSPITAL, GREAT PORTLAND STREET, LONDON, W.

MR. PRESIDENT, VICE-PRESIDENT, AND FELLOWS,—I wish to express my deep sensibility of the honour you have conferred upon me in electing me as one of your Hunterian professors this year. The subject which I have with your consent chosen for this lecture is one which I feel sure would have appealed to that indefatigable worker in whose memory these lectures are established, and my aim will be, as a humble follower of John Hunter, to endeavour to correlate certain pathological facts in a new light.

When investigating any of the diseases affecting the joints of the human body the investigator is at the very outset hampered by the nomenclature of his subject: rheumatoid arthritis, osteo-arthritis, rheumatic gout, arthritism, polyarthritis, to cite a few of the hundred names applied to disease of the joints. In the earliest writings upon medicine, gout and rheumatism were confused and regarded as manifestations of one disease; in fact, Sydenham[1] was of the opinion that rheumatism was a modern disease and unknown to the ancients.

It is not necessary for the present purpose to critically survey the various divisions and subdivisions of diseases of the joints. A summary of the terminology and an epitome of the history will be found in Llewellyn Jones's[2] book on arthritis deformans.

## REMARKS ON ETIOLOGY.

Recently the leaning of most writers has been to regard swellings affecting the joints as divisible into (*a*) those affections which have their primary lesions in the capsule and peri-articular tissues; and (*b*) those in which the seat of the lesion is in the cartilages and bony portions of individual joints. Broadly speaking, the first group, comprising affections of the peri-articular tissues, are generally regarded as of infective origin due to bacteria, either within the joint itself or to a toxin produced by organisms in some other part of the body; as Llewellyn Jones points out, many cases of arthritis in which a bacteriological examination is negative closely resemble the cases of ascertained microbic origin, not only as regards the character of the local arthritic change, but also the general aspect of the patient, the mode of onset of the disease, and its clinical course and behaviour under treatment. The second group, in which the disease apparently commences in the bony and cartilaginous structures of the joints, is not usually considered of direct infective origin.

Goldthwait[3] attaches great value to X ray photographs in differentiating infectious arthritis from that of his two other varieties, atrophic and hypertrophic arthritis, but Kienboch,[4] and more recently Lindsay,[5] have shown that in gonorrhœal arthritis the bones may not preserve their normal density. It is not only in gonorrhœal arthritis, however, but even in ordinary septic processes without any definite arthritic affection, that thinning and alteration in the density of the bone take place. Moreover, a septic process of low virulence, but of long-continued action, in the mouths of human beings invariably produces alteration in the density of the bone in the neighbourhood of the infecting process, as the accompanying radiograph shows (Fig. 1) The infection is not by any means always associated with a copious discharge of pus, but, as I pointed out in my Erasmus Wilson lecture in 1907,[6] loss of density (rarefaction) takes place without the discharge of pus into the mouth, and such rarefaction may be accompanied by sclerosis.

For some years the belief in the infective origin of arthritis deformans has been gaining ground, more especially with that group of cases usually described as rheumatoid arthritis. The initial joint disturbances in acute polyarthritis caused by the gonococcus, the acute onset of rheumatoid arthritis in which no organisms have been found, and the onset of acute articular rheumatism, exhibit similarity; and further, the changes in the joints found in acute polyarthritis of demonstrable infective origin are closely related to the joint changes in which after careful bacteriological search no infecting agent was found.

It is fully admitted that clinically an unbroken progressive series may be established from osteo-arthritis of unknown origin through rheumatoid arthritis, infective polyarthritis, to acute rheumatism, although individually each may be differentiated by certain typical symptoms. But it seems also an equally logical supposition to assume that such a series of cases, although perhaps not owing their cause to a common specific infective agent, may yet be due to infective agents possessing differing degrees of infectivity or virulence.

To sum up this preliminary survey of the subject, a large number of cases of arthritis deformans, using the term in its inclusive sense, are now recognised to be of infective origin, others are of definite neural origin, but between the two are a considerable number which, according to some observers, may be infective, according to others atrophic, neural, or even idiopathic.

## CLINICAL EVIDENCE.

For some time my attention has been drawn to the presence of various so-called rheumatic symptoms in persons subject to disease of the jaws, particularly the type of disease known as pyorrhœa alveolaris, and associated with a discharge of pus from the gum margins and rarefaction of the alveolar process, and frequently the body of the bone. Lindsay in 1908 gives a report of 172 cases of rheumatoid arthritis in which particular inquiry was made for infective foci. In 88 of these cases an infective focus was found, 15 being men and 73 women, and 19 of the 73 women had definite pyorrhœa alveolaris. Lindsay further states that in the majority of the 172 cases some inflammation of the mouth existed, but only those cases where definite pus was to be found were included as pyorrhœa alveolaris. Lambert[7] in the same year says that of 190 cases 141 (76 per cent.) had badly decayed teeth or the teeth had dropped out and 49 (23·8 per cent.) showed teeth in fairly good condition; these latter were the younger patients. For many years pyorrhœa alveolaris was classed by the majority of surgeons as "gout in the mouth," and even amongst dental surgeons a special anatomical form of tooth is often referred to as a "gouty" tooth, and it is worthy of note that the particular gouty or rheumatic tooth so-called is invariably one in which the antero-posterior diameter of the crown is greater than the antero-posterior diameter measured at the gum margin; such teeth are liable to permit the accumulation of food in the interstitial spaces, to injuries of the gum and periosteum, and therefore to local infection. Strange as it may sound, I have often heard the pus oozing from the gum margins ascribed to the patient's rheumatic diathesis.

Two main types of disease of the alveolar processes of the jaws may be distinguished in relation to rheumatic affections:—(*a*) Easily bleeding hypertrophied gums, wasting of alveolus, discharge of pus from the alveolar margins. Loosening of all or individual teeth. (*b*) Thickening of the alveolar process (sclerosis) with area of rarefaction between individual teeth; alteration in position of individual teeth without loosening; showing atrophic gums, little or no discharge of pus. Microscopically pus may be found. In the more common types of mouth infection, where copious discharge of pus is found, where

the teeth themselves become altered in position and length, and which become entirely loosened owing to the destruction of their sockets, the appearance of the bone in the neighbourhood of the tooth sockets is one of a general rarefying osteitis. This is perhaps the more common type. The accompanying skiagraphs show the extent to which rarefaction and perosis of the bone may occur, extending in some cases into the body of the bone itself. [A series of X ray photographs were shown illustrating this point.] As this rarefaction commonly gives no pain, the patient's attention is usually not called to the distressing condition until the teeth themselves are loose. Occasionally evidence of reparative sclerosis is seen.

I have already drawn attention to the importance of this mouth disease as the origin of certain generalised infections, but the peculiar import of alveolar osteitis in arthritis deformans lies in the fact that the alveolus of the jaw is the position in the body where the bony tissues are exposed to septic infection, while owing to the absence of pain treatment is most often neglected, the insidiousness of the onset more often precludes its early diagnosis, and, perhaps more important still, the infecting organisms become adapted to bony tissues.

Lindsay states that in the Royal Mineral Water Hospital at Bath particular attention is paid to the presence of infective conditions of the mouth, and cites two cases where the removal of the septic teeth arrested but did not cure progressive disease of the joints. Llewellyn Jones discussing diagnosis says: "Strong presumptive evidence of infectious arthritis may be drawn from the presence of any local source of infection, such as pyorrhœa alveolaris, otorrhœa, and so forth," and MacNamara [8] states that he had traced many cases to the chronic poisoning of septic teeth. Luff,[9] Spender,[10] Fayerweather,[11] and many others consider the gastro-intestinal tract as the origin of infection, while Hunter,[12] myself, and others have demonstrated the relationship of oral sepsis to gastro-intestinal affections. It is truly said that septic diseases of the mouth are remarkably common and that relatively arthritis deformans is rare; but, on the other hand, I can confirm Grünbaum's [13] experience that few, if any, cases of arthritis deformans have sound mouths. Further, the bacteria I have isolated from the mouth do not, as a rule, possess a high degree of virulence even when injected in large doses into laboratory animals, and it is not illogical to suppose micro-organisms of a low type of virulence habituated to the environment of bony tissue and peri-articular structures would be more likely to act as infecting agents in chronic processes than organisms possessing a high degree of virulence. This supposition receives considerable support from my own investigation, before detailing which it is necessary briefly to consider the present bacteriological knowledge of rheumatoid arthritis.

## BACTERIOLOGY.

The earliest bacteriological work on Arthritis Deformans is that of Schüller,[14] who obtained fluid from the joints in a type of arthritis deformans clinically associated with early atrophy of the muscles, thickening of the synovial membranes of the joints and peri-articular structures, termed by him as *polyarthritis chronica villosa bacillaris*. Schüller described certain short bacillary forms which were easily decolourisable by the staining methods he used; in a later publication he says the organism stained by Gram's method. The organisms were found but rarely in the joint fluid, their seat of selection being the capsule and other structures outside the joint. Cultures were obtained by allowing fluid from the joint to drop through a cannula on to the culture media, or by triturating portions of the thickened synovial membrane or capsule and inoculating from the mass on to culture tubes. Schüller's bacillus produced greyish-white discrete colonies on agar in from two to six days, and grew readily on gelatin which was slowly liquefied. The organism remained alive on culture media for several months, retaining its virulence. Subcutaneous injections of 0·5 gramme to 1 gramme in rabbits were fatal in 24 hours; injection of a similar quantity into a joint produced swelling only, which became permanent in character, and resulted in a persistent limp. No pus was found in the joints, but the synovial membrane in places showed villous and brown fringes, sections of which were shown to contain the injected organisms. They were polar-staining bacilli which formed spores. Cocci were often found together with the bacilli, but were not regarded as playing an important part.

The next bacteriological work was that of Blaxall [15] in 1896, who examined fluid aspirated by Bannatyne from the joints in rheumatoid arthritis and found that by prolonged staining in concentrated solutions an organism could be demonstrated in the synovial fringes. This organism showed marked polar staining, the average length was 2$\mu$, and the average breadth 0·6$\mu$. Sometimes large numbers were found congregated round leucocytes. The organism almost completely decolourised by Gram's method, but not absolutely. Only two out of the 18 cases he examined showed organisms referable to skin contamination. He also examined a number of joint fluids in chronic synovitis, gonorrhœa, and other affections, without seeing this special form of organism. Attempts at cultivation were at first unsuccessful, but finally a growth was obtained on beef broth, in the form of a slightly flocculent deposit compared to gold dust. The bacilli were 3 to 4$\mu$ in length and showed the same polar staining as in the direct smears. No chains were seen. Upon agar the colonies developed very slowly, and were never larger than a pin's point. The bacilli grew on milk without producing acid or precipitating the casein. Intravenous inoculations into animals produced no definite reaction, and the animals recovered; slight swelling of the inoculated joints was observed in two instances which, however, cleared up. Both Bannatyne [16] and Schüller's cases were ones in which no bony or cartilaginous changes were present.

Kroh,[17] in his paper on Experimentelle Arthritis Deformans, gives an account of a number of cases of arthritis deformans which were produced experimentally in animals (rabbits). The method adopted was the resection of a portion of the joint, leaving the joint itself unaffected by septic processes, but partially out of action, due to the removal either of portions of the condyles or other anatomical parts of the knee-joints. No suppuration followed the small operation, but skiagrams taken at intervals after the operation showed a progressive change had taken place in the joints, causing hypertrophy of the remaining articular surfaces and the bony tissues supporting them, and producing a certain amount of swelling and deformity of the external portion of the joint.

Poynton and Paine,[18] Ainley Walker and Beaton,[19] and Beattie made cultures from cases of acute rheumatism. Poynton and Paine described a *streptococcus rheumaticus* found in the lesions of rheumatic fever, and which, when inoculated into animals, produced infective endocarditis, but they say they have never personally found the occurrence of this coccus in the joints of human beings. Beattie gives the result of cultures made from a case of acute rheumatic fever, which died six days after admission to the Royal

## DESCRIPTION OF ILLUSTRATIONS.

FIG. 1.—X ray photograph showing loss of alveolus; the dotted line shows the normal alveolar line.

FIG. 2.—Forty-eight hours' egg agar culture streptobacillus malæ. × 1000. This photograph shows the involution forms; one is situated at the end of a chain, bacillary and coccal forms.

FIG. 3.—Streptobacillus malæ, 24 hours' agar culture, showing bacillary form.

FIG. 4.—Four days' agar culture of streptobacillus malæ, showing the degeneration into chains of bacilli and a large irregular involution form in the centre of the field.

FIG. 5.—Forty-eight hours' old colony of streptobacillus malæ on agar. × 3.

FIG. 6.—Right and left knee-joints of a rabbit inoculated in May, 1910, pure culture of streptobacillus. The photograph was taken from the back of the joint, the animal lying on its face. It will be seen that the right knee, the head of the tibia, shows alteration in the outline of the cartilage, some erosion of the lower end of the femur on the left-hand side, and the whole of the upper part of the head of the tibia shows signs of thickening. Comparing the outline of the cartilage of the sound limb on the opposite side the change can easily be seen.

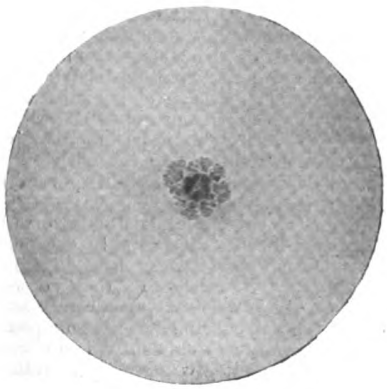
FIG. 5.



Infirmary, Edinburgh. Subcultures of the organism obtained from the joints of the case were inoculated into animals intravenously, the amount used being two whole agar tubes. The organism was recovered in pure culture from the tissues of the animals afterwards, the injections having produced arthritic changes in four days. Two animals were inoculated in the knee-joints, producing definite arthritis of an acute type which gradually subsided but never disappeared, the animals ultimately regaining their normal health. No visceral lesions were found at the necropsy, but some thickening and infiltration remained round the joints. Cultivations from the fluid and from the cartilaginous surfaces were sterile. For the control, streptococci obtained from the vegetation in a case of malignant endocarditis were inoculated into the knee-joints of two rabbits. The rabbits died from streptococcal septicæmia with no trace of arthritic changes.

In 1903 Beaton and Ainley Walker described the cultural characters of an organism, a *streptococcus*, found in acute rheumatism. This was also found in cases of acute rheumatism, chorea, and endocarditis. They considered it similar to that found by Paine and Poynton, and Beattie. Large doses of the organism produced death within 40 hours in rabbits, six or more agar cultures being used. Moderate doses caused effusion of the joints and tendon sheaths, and death up to as late as three weeks, whilst small doses of the organism obtained from rabbits dead from infection with the streptococcus produced polyarthritis in animals (rabbits).

In 1907 Walker [20] again returns to the subject, and comes to the conclusion that the organism is a streptococcus differing in some respects from the ordinary streptococcus pyogenes.

It will be noted that the last three or four observers when dealing with acute infection of rheumatic fever type found that the organisms produced an acute polyarthritis which cleared up practically without a permanent lesion in the joints, similar in this respect to the lesions of rheumatic fever in the human subject.

Fayerweather worked at the bacteriology of arthritis deformans, his cases belonging to Schüller's type of polyarthritis. Fayerweather investigated four cases, in all of which were found *bacilli*, pleomorphic in type, alternating between long rods with slightly rounded ends, and diplococcal or lanceolate forms, which ultimately grew out into definite bacilli. Two of the organisms produced liquefaction of blood serum, but the other two did not. Of the two which did not produce liquefaction, one was non-motile and the other motile, and the non-motile one was not found to produce spores. The organisms differed slightly in their morphological and cultural characters. Ten rabbits were inoculated from the cultures, either intravenously, subcutaneously, or into the knee-joints. Subcutaneous and intraperitoneal inoculation produced no effect whatever. Three rabbits were inoculated with cultures of the first organism, a bacillus which produced some slight changes when inoculated into the knee-joints, whereas the third organism, a diplococcal form, produced a uniform thickening of the synovial capsule. No changes were seen in the bones, and no muscle wasting, and the animal was apparently quite normal.

A point of some importance in Fayerweather's work is that although the organisms produced no effect when inoculated subcutaneously or intravenously, in several instances change did occur in the joint, the synovial fringes being the chief structure affected.

The bacteriological findings in articular rheumatism may be divided into two series, the one *acute*—in which Poynton and Paine, Ainley Walker and Beaton, and Beattie all agree in finding *streptococci*; and *chronic* in which Schüller, Bannatyne, and Fayerweather found organisms of *bacillary types*, Schüller and Fayerweather both having produced lesions of the joints of rabbits by inoculation with cultures of the isolated bacilli.

One other observer remains to be cited—namely, Painter [21]—who treated nine cases of rheumatoid arthritis with vaccines prepared from the organism described by Fayerweather and claimed by Schüller to be identical with the one he first described. Unfortunately, no reference is made to which of Fayerweather's organisms was used. The opsonic index to the organism was low in every case tested, but a stock, and not an autogenous, vaccine was used. No improvement was observed in any of the cases treated, although a definite exacerbation of the local joint symptoms followed the injection of the vaccine in all the cases.

With the foregoing survey of the subject, I now turn to my own researches on the

### ESPECIAL RELATION OF RAREFYING ALVEOLAR OSTEITIS TO ARTHRITIS DEFORMANS.

The amount of destruction of the bony tissues in the jaw is often out of all proportion to the severity, or apparent severity, of the infection, and even when pus is found welling up from the gum sockets one cannot fail to be surprised at the amount of deep infection the bone has sustained.

The following X ray photographs taken for me by my friend Mr. Reid exhibit the loss of tissue and rarefaction particularly well. [A series of X ray photographs of the jaw were shown illustrating this point.]

Fig. 1 shows in the lower jaw the extreme destruction which may take place; not only the alveolus has been lost, but a distinct cavity has been formed in the body of the bone reaching downwards into the inferior dental canal. The bicuspid is also deeply infected. In the upper jaw some attempt has been made at repair. The photographs are merely examples of a large number which might be adduced to show the ravages that take place in the hard tissues of the jaw under the influence of chronic suppurative lesions. It must be noted also that in many cases there was little pus to be found. In Case 3 particularly it was only with the greatest difficulty and even on microscopical examination that definite pus was to be demonstrated. The teeth themselves were not loose, but of course gave definite evidence on physical examination of loss of bony attachment.

The peculiar interest of these photographs is the presence of rarefaction, together with sclerosis. Such a condition in many ways is comparable to arthritis deformans, and was the starting-point of my inquiry as to the possibility of the production of experimental arthritis deformans in animals by the use of the organisms, which evidently possessed a peculiar predilection for destruction of bony tissues.

In the first stage of my experiments I attempted to reproduce disease of the joints by the intravenous inoculation of organisms isolated from such cases as the ones shown in the X ray photographs. To begin with, the pus itself was used for inoculation into rabbits intraperitoneally, subcutaneously, and intravenously. Only a few of these experiments are given in the table of animal experiments, as in all instances in which such inoculation was performed no inflammatory reaction was produced in the joints. Localised suppuration indeed was formed in many instances, and in not a few cases the animals died sometimes from toxæmia, sometimes from generalised infection. Attempts were therefore made to determine which of the horde of bacteria in the pus were the infecting agents. Resource was had to agglutination, the opsonic and phagocyte index, estimations both before and after massage of the affected parts, and to direct animal experiments. A number of organisms were isolated, certain of which undoubtedly produced local suppuration when inoculated subcutaneously, and it was thought that perhaps these were the most likely to give positive results. The method described by Beattie was made use of, animals were inoculated intravenously with cultures of the organisms, and the animals afterwards exposed to cold. Beattie, who made use of this method, found that certain animals which he had injected with streptococci obtained from rheumatic cases exhibited signs of arthritis when the temperature of the laboratory in which they were housed went down to freezing-point during temporary damage to the heating apparatus. None of my animals exposed to cold after inoculation showed signs of arthritis.

Most of the organisms obtained from the alveolar processes are non-motile, and therefore the method of agglutination did not give particularly satisfactory results, and was abandoned.

The estimation of the opsonic index gave rather better results, but it was found that not only one organism, but often four or five different species isolated from the gum margins underwent variations in their opsonic index, particularly when the blood was taken before and after the operation of scaling and cleaning out the gum pockets.

Amongst the organisms isolated from the gum margin one in particular seemed to give more variation in its opsonic index than any of the others. This organism was at first

[20] Brit. Med. Jour., May 25th, 1907, p. 1233.
[21] Boston Surgical and Medical Journal, Nov. 7th, 1907.

regarded as a Gram-negative streptococcus, but as Gram-negative streptococci are exceedingly rare a good deal of attention was given to its morphology. It was found on careful examination that the organism in question differed very much in its general morphology, and in a certain number of other particulars, from the ordinary streptococcus of the mouth.

It is true that streptococcal forms exist in many instances and, as will be seen in Fig. 2, a fairly well-marked streptococcal form is seen, but with a tendency to elongation of the individual elements. Not only this, but there is definite irregular staining, giving the suggestion of polar-staining bacilli. This polar staining is much better demonstrated with Löffler's blue. It is, of course, known that streptococci when grown for any length of time in the laboratory have a tendency to form bacillary types; and it is also well known, as pointed out by von Lingelsheim in Kolle and Wassermann's "Handbuch der Pathogenen Microorganismen," that alternations of bacillary and coccal forms are not uncommon in streptococcal chains giving the well-known appearance of a Morse alphabet. Further, when growing badly or on unsuitable media, and particularly on potato, the streptococcus rapidly involutes and produces a variety of irregular involution forms, so that the difficulty of distinguishing the streptobacillus from the streptococcus is very great. Nevertheless, after a considerable amount of investigation and the staining of a large number of films in various ways I have finally come to the conclusion that the organism which I am describing is a streptobacillus. Its closest morphological relation, as far as I can discover, is the streptobacillus of ulcus molle described by Ducrey, and the drawings given in Kolle and Wassermann's "Handbuch," p. 434, and particularly p. 429, in which the involution forms are given, are in almost every particular identical with the morphology of this organism.

### MORPHOLOGY.

When growing freely the organism is like Ducrey's bacillus, a definite streptobacillus, but in colonies taken direct from the plates on first plating a diplobacillary form is common. (Fig. 3[22]). At first sight these diplobacilli closely resemble diplococci, but if care is exercised, particularly in staining by Löffler's methylene blue, it will be seen that the organisms are in reality small diplobacilli with well-marked polar staining. Young cultures (12 hours) stain by Gram's method, but the organism very rapidly loses the power of Gram-staining and except for the larger involution forms and for here and there scattered granules in individual organisms, decolourisation takes place; in fact, this peculiarity first led me to regard the organism as Gram-negative, but the question of Gram-staining is entirely one of the age of the culture. In the older cultures, and even in some of the younger cultures where the organism is not growing freely, there are certain curious forms which may or may not be regarded as involution forms, and they may be divided into three types: 1. Large, oval, swollen forms, 2 to 3$\mu$ in width, and showing a marked transverse striation when stained with Löffler's blue, the ends frequently pointed, but may be rounded. 2. Large coccal forms, 2 and even 3$\mu$ in diameter, irregular in shape and associated in clusters. (Fig. 4.) 3. Oval, elongated, and shuttle-shaped forms occurring frequently in the length of the chain, taking the stain for the most part deeply. At times these pointed swollen forms are seen at the termination of a thread, and they may exhibit transverse striation. (See Fig. 2.)

The various photographs show the pleomorphism that may be met with. Fig. 3 gives very frankly a diplobacillary form which is common in freshly isolated cultivations. Fig. 4 gives the streptobacillary form, showing, amongst other characters, the tendency to swollen elements in the thread, large swollen and irregular involution forms. In Fig. 4 particularly one large involution form is seen in the centre of the field. In the centre of the field of Fig. 2 a large irregularly stained form is seen at the end of one of the threads. Figs. 3, 4, 5, and 6 are from the same cultivations taken at different days. The organism may, I think, with propriety be termed pleomorphic, but there are other characters than the pleomorphism which tend to divide it from the streptococci.

[22] This name suggested for the organism as identifying it with the jaw lesions, from Lat. mala—the jaw bone.

### CULTURAL CHARACTERS.

Fig. 5 is a 48-hours old colony of the organism on agar, and gives the typical form of this organism. It will be seen at once that it differs from the ordinary streptococcal colonies, which are regular, hyaline, and faintly granular. It may, perhaps, bear some sort of resemblance to the colonies of the pneumococcus, but the organism itself in no way resembles Fraenkel's organism. The organism is a facultative anaerobe, and grows best of all in deep stab cultures on agar. Seemingly it requires a small percentage of oxygen present as it grows much better in the depths of a glucose formate stab than it does on a glucose formate streak in an atmosphere of hydrogen. The reaction of the medium is another important factor. No growth takes place at all on media + 10 or neutral. + 3 is the optimum reaction. Nutrose and ascetic agars both give fair development, but by no means as good a growth as agar made with egg albumin. On broth little or no growth is seen; generally a small quantity of precipitate collects at the bottom of the tube, but no flakes are seen down the sides of the tube, and general turbidity of the medium rarely takes place, neither is any pellicle formed.

I find that notwithstanding considerable care the organism dies out with provoking rapidity, and that unless constant subcultures are made on alkaline agar the cultures die out in about a week's time. They die out more rapidly at the temperature of the room than they do at blood heat; in fact, I find from experience that a week's residence at 15° C. almost invariably results in the death of the organism. The thermal death-point is 52° C. for half an hour. The organism in many respects resembles the streptococci in its fermentation of carbohydrates, as will be seen on reference to Tables I. and II. of the cultural characteristics of a number of organisms isolated. There appears to be no definite regularity in the carbohydrate fermentation, with the exception of the inability to ferment caffeine and manitol. Of the carbohydrates tested, salicin and inulin are less frequently fermented than sucrose; the organism always ferments glucose, only a few races do not ferment lactose. Litmus milk is rendered acid, and in the majority of cases coagulated. No visible growth occurs on potato at 20° C., but at blood heat a development may occur on potato producing a slight shiny, whitish appearance. No indol is produced, no sulphuretted hydrogen, and no reduction of nitrates to nitrites, there is no chromogenesis, and the organism grows on blood serum poorly and does not produce any liquefaction of the medium. There is no alteration in neutral red broth, aerobically or anaerobically, in four days. The growth on gelatin is feeble and fails generally. In agar cultivations the growth rarely takes the form of a definite streak, but almost invariably discrete colonies appear over the surface of the medium, and on egg albumin agar may develop to two or even three millimetres in diameter. This medium I find the most suitable for the isolation of the organism. The colonies have a curious pearly lustre when viewed with transmitted light both on agar and egg agar. The growth on agar is generally well marked in the condensation water, where a thickish nummular precipitate makes its appearance. On the surface of the medium, however, considerable variations exist in the cultural appearances, some of the cultures closely resembling streptococci. When the culture is removed for examination with the spatula the mass is frequently found to be of a dry, flaky consistency, and in making vaccines much difficulty is experienced owing to the tenacious way in which the colonies cling together; prolonged shaking in an electric shaker is necessary to produce an efficient emulsion.

Two other bacillary types were selected for examination; these showed a good deal of opsonic index variation. The cultural characters of one group appear in Table I. of cultures inoculated, as these three organisms were used for inoculation, and produced slight, but definite, joint swellings when inoculated into rabbits. Two other types of organisms were also tested by animal inoculation—namely, the Gram-negative cocci of the mouth, belonging to the group *Micrococcus catarrhalis*, and the *Micrococcus citreus granulatus* of Freund, but with negative results.

### INOCULATION EXPERIMENTS.

The intravenous, subcutaneous, and peritoneal inoculations into rabbits of the streptobacilli or other organisms

produced no effect or symptoms of arthritis in rabbits (see Table III.). At the suggestion of Mr. Clement Lucas I proceeded to the direct joint inoculation, with the result that symptoms indistinguishable from arthritis deformans have been established in 18 rabbits. The organisms which have produced this joint change have in 15 instances been the streptobacillus of the type the cultural characters of which are given in Table I., but differing from one another in certain particulars with regard to their carbohydrate fermentation and their growth on litmus milk (see Table I.); but both these media are ones in which organisms exhibit peculiarities not sufficient to differentiate them into definite species. In three rabbits a slight amount of joint change has resulted from the inoculation of the organisms given first in the table of cultural characteristics (Table I.), but in no case has the swelling or effect upon a joint been so marked in degree nor so definite as with the streptobacilli.

as the inoculation. Distinct wasting of the extensor muscles was also seen, and the joint became slightly flexed when the animal was at rest. In a number of other instances animals inoculated later than this one, particularly in three animals which were inoculated in January of this year, semi-flexion of the inoculated joint has already occurred.

Mr. Reid kindly obtained X ray photographs of a number of these animals for me, and I wish to tender him my sincere thanks for the trouble which amongst other things entailed transporting much apparatus to the laboratory for the purpose of taking the photographs of these experimental animals.

Fig. 6 shows the antero-posterior view of the right and left knees of the arthritic rabbit. The head of the tibia and the lower end of the femur on the outer side both show alterations in the cartilage and commencing destruction of the articular surfaces of the joint, but the photographs, of

MORPHOLOGY
- A—Nos. 1–3 & 23. Bacilli irregular and diplo-, faintly staining with ordinary stains; red granules in three-day cultures with methylene blue.
- B—Nos. 4–22 & 24. Bacilli, oval-pointed and spindle-shaped, coccal forms common, diplo- or strepto-bacilli, large, irregular, and swollen involution forms, these taking Gram's stain darkly, other forms often decolourised.

COLONIES
- A
  - Microscopically: Undulate or entire, marmorate, coarsely granular.
  - Macroscopically: Round medium, opalescent, opaque, raised, moist.
- B
  - Microscopically: Lacerate or lobate, sometimes lobulate, hyaline with grumous centre, or with irregular central darker area.
  - Macroscopically: Transparent and translucent, with opalescent sheen, slightly irregular or undulate, occasionally with central point.

C. M. B. = Carbolic methylene blue. A = Acid reaction. + = Complete reaction. ± = Slow and feeble reaction. — = No reaction.

In Table III. I have summarised as far as possible the inoculation experiments of 33 animals, which have been injected with cultures of the organisms I have been discussing. Case 34, Rabbit 10, was inoculated in May, 1910, with an emulsion of 0·5 c.c. of a 24 hours' culture of a streptobacillus (432 C). This organism was a typical variety of the streptobacillus, showing the curious shuttle-shaped involution forms and the long streptobacillary forms. On May 26th there was well-marked thickening of the capsule with some creaking in the joint, which was swollen, but not tender nor greatly thickened. The knee-joint progressively increased in size, and on Jan. 13th, 1911, there appeared to be some slight thickening of the knee-joint on the opposite side, and at the same time there was also to be felt a slight thickening of the ankle-joint on the same side

course, do not show the alterations in the synovial structures. The joint itself is typically that of arthritis deformans, the photograph being taken nine months after inoculation, only one injection having been made. The alteration in the head of the tibia and the thinning of the tuberosity are definitely shown. There appears also from the photograph to be some sclerosis in the head of the tibia and the lower end of the femur, recalling to some extent the rarefaction associated with sclerosis shown in the earlier photographs of the local disease of the jaw. A small foreign body is to be seen on the outer side of the joint and to-day there appears to be the commencement of osteophytic nodules around the margin of the head of the tibia.

Another rabbit was inoculated on the same day of May, 1910, but with a culture of a streptobacillus obtained from

another case. Well-marked swelling occurred on the outer side of the joint at the end of a month, and in four months' time the right knee was still slightly swollen. On Dec. 5th the animal was inoculated again, this time with a whole agar culture from another case exhibiting rheumatoid symptoms, but in this instance in the ear vein and not locally. No increase of swelling took place in the knee-joint; in fact, some improvement occurred for a short time. On Jan. 25th the animal was reinoculated on the outer side of the same joint with 1 c.c. of an agar emulsion in 1 c.c. sterile saline, care being taken that no fluid went direct into the cavity of the joint. The inoculation was followed by considerably increased swelling of the joint, which by Feb. 20th was much thickened, so much so that the animal was unable to extend the leg at the knee, and the knee-joint was held flexed. On Feb. 13th a skiagraph was taken by Mr. Reid, and very little change is to be seen in the skiagram notwithstanding the fact that well-marked thickening of the synovial membrane and the capsule were to be felt. The dissection of this joint and the uninoculated joint on the other side of the body are on the table, and show the thickened capsule and swollen synovial fringes as well as commencing destruction of the joint with bony and cartilaginous changes. The appearance of the skiagraph suggests some alteration in the right knee-joint, but very much less than in the other rabbit. These animals were inoculated from cases in which arthritis deformans was a definite symptom, but I have found that the streptobacillus is by no means confined to such mouths as have rheumatoid arthritis.

Rabbits Nos. 15 and 30 are two instances of knee-joint inoculations, Rabbit No. 45 of intracapsular inoculations, Rabbit Nos. 47 and 49 of extracapsular inoculation with 0·5 c.c. of saline emulsion of the streptobacillus obtained from persons who were apparently in normal health, but who had rarefying osteitis of the jaw.[23] It will be seen that these animals exhibit well-marked swelling and deformity of the right knee-joints. These animals have received only one inoculation, and Rabbit No. 47 was inoculated with a culture, photographs of which I have shown on the screen.

## CASES.

In going over my records of cases of diseases of the mouth I find that in the last 263 uncomplicated cases of varying degrees of infective processes of the alveolus, excluding all cases of growth and such cases as had complications, i.e., as antral disease and all other similar infections, 49 gave a definite history of rheumatic symptoms. These cases were divisible into three main groups, but of course shaded imperceptibly one into the other.

[23] These animals were exhibited at the lecture.

### TYPES OF CASES.

*Group A.*—Definite arthritis of one or more joints, with pain, swelling, limitation of movement, and with or without wasting of one or other muscles in the neighbourhood of the joint. Swelling of tendons or tendon sheaths in the neighbourhood of joint or elsewhere. Muscular pains, diffuse and irregular in distribution and origin. Neuralgia of trigeminal type. Anæmia.

*Group B.*—No definite arthritis; inflammation, or swelling of tendon sheath or tendon. Diffuse muscular pains, irregular in distribution and origin. Occasional swelling of joints or tendons, clearing up and leaving no objective symptoms. Palpitation, with irregularity of heart action. Tachycardia. Neuralgia, trigeminal type. Sciatic pain not definitely referred to the sciatic nerve, but diffuse and referred. Gastric and intestinal symptoms.

*Group C.*—Occasional swelling and tenderness in joints or tendons, rapidly clearing up and leaving no objective symptoms. Irregular muscular pains, occasionally associated with stiffness. Tingling, or "pins-and-needles" sensation in extremities. Local asphyxias or other vasomotor phenomena. Intermittent lumbago. Occasional trigeminal neuralgia.

These three types gave respectively 25, 16, and 8 cases. Of the total number of cases with a history of rheumatic symptoms, 15 were males and 34 females. A brief synopsis of the 49 cases is appended.

TABLE III.—*Inoculation Experiments.*

| | No. of case. | Organism. | Animal. | Dose. | Site of inoculation. | Result and notes. |
|---|---|---|---|---|---|---|
| Mouth suppuration, with symptoms of rheumatism. | 2 | Diplobacillus (2). | Rabbit. | 1·0 c.c. | Right knee-joint. | No suppuration; 20 days, globular swelling of joint; 2 months almost disappeared. |
| | 4 | Streptobacillus (4). | Mouse. | 0·3 c.c. | Subcutaneously. | No suppuration; recovered. |
| | 14 | ,, (4). | Rabbit. | 0·5 c.c. | Right knee-joint. | No suppuration; 2 months, no change in joint. |
| | 16 | Streptobacillus. | Mouse. | 0·5 c.c. | Subcutaneously. | No suppuration; recovered. |
| | 16A | ,, | ,, | 0·5 c.c. | ,, | ,, ,, |
| | 17 | ,, (8). | Rabbit. | 0·5 c.c. | Right knee-joint and intravenously. | No suppuration; swelling of knee-joint for 48 hours; recovered. |
| | 21 | ,, (5). | ,, | 1·0 c.c. | Right knee-joint. | No suppuration; 2 months later, joint much swollen, tender, crepitus, synovial membrane thickened. |
| | 24 | Diplobacillus (3). | ,, | 1·0 c.c. | ,, | 7 days, fluid in joint, capsule swollen; 40 days, still some swelling outer side of joint. |
| | 31 | Streptobacillus (6). | ,, | 0·5 c.c. | Right knee-joint and intravenously. | Small external abscess; no fluid in joint in 10 days; recovered. |
| | 32 | Streptobacillus (urine) (9). | ,, | 0·5 c.c. | ,, | 7 days, much thickening upper end tibia; 6 weeks, general globular thickening of joint. |
| | 34 | Streptobacillus (10). | ,, | 0·5 c.c. | Right knee-joint. | No suppuration; progressive enlargement of joint, much thickened; muscular wasting; bone affected 10 months later (see X ray photo). |
| | 35 | ,, (11). | ,, | 1·0 c.c. | Subcutaneously. | Local tissue necrosis; recovered; organism obtained in pure culture, reinoculated; abscess formation; recovered. |
| | 36 | ,, (13). | ,, | 2·0 c.c. | ,, | Local suppuration, with thick caseous pus; organism recovered 7 days later, pure culture; recovered. |
| | 38 | ,, (12). | ,, | 1·0 c.c. | Right knee-joint and intravenously. | 3 days, joint swelling; 2 months, persistence of joint swelling and thickening (?); symptoms slight. |
| | 40 | ,, (1). | ,, | 1·0 c.c. | ,, | 3 days, joint swelling; 20 days, globular; 40 days, swelling almost disappeared. |
| | 40A | ,, (1). | ,, | 1·0 c.c. | Intravenously only. | No change; animal recovered. |
| | 44 | ,, (14). | ,, | 1·5 c.c. | Right knee-joint and intravenously. | 7 days, thickening of joint; 10 weeks, definite thickening of bones, but capsule of joint not affected. |
| | 44A | ,, (15). | ,, | 0·5 c.c. | Right knee-joint, external to joint. | 7 days, general swelling of joint with some capsular thickening; 2 months, swelling less but present. |
| | 49 | ,, (7). | ,, | 0·75 c.c. | ,, | One month, general swelling, no pus formation; joint flexed; synovial membrane and capsule thickened. |
| Mouth suppuration, with no symptoms of rheumatism. | 50 | M. citreus granulatus. | ,, | 0·3 c.c. | Right knee-joint. | No suppuration, no swelling of joint; recovered. |
| | 51 | Streptobacillus (16). | ,, | 0·5 c.c. | Right knee-joint and intravenously. | No suppuration, swelling of joint, and capsular thickening; 10 months later no swelling. |
| | 52 | ,, (17). | ,, | 2·0 c.c. | Right knee-joint and intraperitoneally. | No suppuration, swelling of joint and capsular thickening 5 months later. |
| | 53 | ,, (18). | ,, | 1·0 c.c. | Right knee-joint external to joint. | 20 days, swelling of joint and abscess in calf muscles, pus aspirated, culture sterile. |
| | 54 | ,, (19). | ,, | 1·0 c.c. | Right knee-joint. | 14 days, swelling and partial fixation of joint. |
| | 55 | ,, | ,, | 0·5 c.c. | Intravenously. | No signs of infection; recovered. |
| | 56 | ,, (20). | ,, | 1·0 c.c. | ,, | ,, ,, ,, |
| | 57 | ,, (21). | ,, | 1·0 c.c. | ,, | ,, ,, ,, |
| | 58 | ,, (22). | ,, | 1·5 c.c. | Intravenously and subcutaneously. | Local abscess, thick pus; animal recovered; organism obtained from pus. |
| | 59 | Pus from mouth. | ,, | 1·0 c.c. | Subcutaneously. | Two abscesses at site of inoculation, streptobacillus recovered in pure culture; recovered. |
| | 60 | Pus from rabbit (59). | ,, | 1·0 c.c. | ,, | No local suppuration, no general infection; recovered. |
| | 61 | Bacillus (23). | ,, | 1·0 c.c. | ,, | Acute local necrosis of skin, which sloughed; no swelling or alteration of joints; recovered. |
| | 62 | Streptobacillus (24). | ,, | 0·5 c.c. | Intravenously. | No symptoms produced; animal well 4 months later. |
| | 63 | ,, | ,, | 1·0 c.c. | Right knee-joint and intravenously. | 1 month, slight capsular thickening, no pus. |
| Control | | Sterile water. | ,, | 2·0 c.c. | Right knee-joint. | 10 weeks, no signs of inflammation or thickening of joint or capsule. |

The numbers in parenthesis under the heading "Organism" refer to the numbers of the organism in Table I.

### NOTES OF CASES.

*Group A.*

CASE 1.—Aged 60. Failing health for several years, with recurrent attacks of swelling in mouth. An acute attack diagnosed as food poisoning two years previously. Has had fleeting swellings in various situations, mostly extensor surfaces of hands, and stiffness in shoulders.

Ulnar deflection both hands. Right index, metacarpo-phalangeal joint swollen. Mouth: condition very bad, much loss of tissue, alveolus absorbed and rarefied. Vaccine therapy. Cured.

CASE 2.—Aged 42. Five and a half years previously had a little rheumatism which became subacute; treated at Buxton three months, much better. Following winter more rheumatism, with swelling in joints, knees, arms, and hands, especially the left, very tender at night, cramps, tingling in calf mostly preceding cramps. Treated again at Buxton and Aixe. Confinement next year in Malta; sore tongue during the time at Malta; child also had sore mouth. Teeth extracted before leaving Malta; acute infection following; was stiff, could not move. Acute attack subsided, joints became less stiff. Present condition: right internal head of tibia thickened, knee full of fluid, much creaking, limitation of movement. Left knee freer movement, but creaking in joint. Thickening along patellar tendon, ulnar displacement of both hands. Mouth: thickening of alveolar margins. Pus present in small quantity; interdental rarefaction of bone. Vaccine therapy. Relieved.

CASE 3.—Aged 30. In September, 1909, was going home from business and got wet through. An acute attack of pain and swelling in most of her joints. Was sent to bed ten weeks, and then to Bath, where she was able to walk with two sticks. Was at Bath until Dec. 24th; not progressed at all. On May 11th, 1910, right knee and ankle swollen; knee, thickening of upper and outer margin of head of tibia, painful on pressure; œdema over shin; pain and swelling of right hip; lordosis, unable to walk upstairs without assistance; can just manage to walk on the flat with a stick, which always brings on pain. Mouth: teeth and gums appear normal; slight ulceration at back of upper central incisors. History of occasional sore mouth, loss of bone between premolars in upper jaw. Pus microscopically only. Vaccine therapy. Cured.

CASE 4.—Pain in back and outer side of left thigh for six years. Three years after commencement thickened synovial fringe diagnosed. Well-marked swelling of left knee, pain in certain positions, tender spot outer and lower side of patella. Mouth: desquamative gingivitis, sclerosing osteitis upper jaw, mild in type; much thickening of alveolus. Pus from three teeth. Vaccine therapy. No improvement.

CASE 5.—Six years ago pain and diffuse swelling right knee and right hand and wrist; pain disappeared, leaving stiffness; joints creaked. Present time unable to use right wrist; thickening of tendon sheath of extensor of hand; slight ulnar displacement. Mouth: teeth have been projecting more and more for some three years. Little suppuration, but thickening of alveolus, slight thickening of alveolar margin. Vaccine therapy. No improvement.

CASE 6.—March, 1906. Right knee large swelling. Droitwich in August. By October nearly well. At the end of October swelling recommenced, and in March, 1907, left knee and left shoulder were also considerably swollen with much pain. Both hands became swollen on dorsal surfaces. In June he went to Aix-les-Bains, did not improve, and was worse afterwards. Was treated at home till beginning of 1908, when he was sent to Teneriffe. During the whole of the time he had been taking iodides. At Teneriffe another acute attack, in which all the joints that had been previously affected became very much worse; had constant smell in nose and mouth, and taste of "burning hair." Unable to walk without the assistance of two people, one on either side. In February, 1909, swelling right and left knees, impossible to feel outline of joint; well-marked creaking in both; ulnar deflection both hands, right hand fingers flexed, cannot straighten without acute pain. All tendon sheaths thickened; both shoulder-joints thickened, creaking, very painful on passive movement. Has lost 2 stone in weight since March, 1906, and a stone during the last year. Mouth: full of gold crowns and bridge work, with discharge of pus from almost every socket. Vaccine therapy. Cured.

CASE 7.—Progressive polyarthritis, remissions and exacerbations, the latter with fever. Pain, wasting of muscles. Mouth: all teeth lost, except two, through pyorrhœa. Not treated.

CASE 8.—Age 45. Three years ago acute pain in left shoulder; swollen; three days in bed; recurrence a year later, associated with cardiac attack; treated at Llandudno; in bed for three weeks. Pain recurred at intervals for three years, occasionally appearing in other joints. Latterly associated with pain, hyperæsthesia and occipital neuralgia. Fusiform swelling of middle and ring fingers of both hands. Swelling external malleolus. Mouth: little or no suppuration, thickened alveoli; teeth recently shifting in position without obvious cause. Vaccine therapy. Cured.

CASE 9.—Local asphyxia with coldness, tingling in both feet at night, right foot "goes to sleep." Tingling in fingers; occasionally left hand becomes quite cold for a short time. Pain in both knees intermittent; swelling synovial membrane right knee; tender round internal tuberosity of left tibia. Mouth: some pus, only found microscopically, but composed of fresh polymorphonuclear cells. Has lost most of teeth owing to progressive loosening. Last few years constant recurrence of water blisters on lips. Vaccine therapy. Relieved.

CASE 10.—Aged 54. Six years' history of neuritis in arms and legs, associated with swelling of tendons in hands, stiffness and creaking in left shoulder. Constant lumbago, occipital neuralgia. Fusiform swelling ring finger of left hand. Mouth: has had receding gums for 20 years. Little pus, alveolus thickened, some loss of alveolus in interdental spaces. Vaccine therapy. Cured.

CASE 11.—Swelling of both knees, thickening of synovial membrane, no apparent alteration in joint surfaces, ulnar deflection of one hand. First noticed rheumatic symptoms five years ago; from that date to the present time has been progressively stiff in all the joints, and with muscular pains, generally worse at night. Quite unable to walk now more than a few hundred yards, even then only with excessive fatigue and pain in joints. Appetite bad, has lost weight; considerable depression. Mouth: considerable pus discharge from gums. X ray photograph shows rarefaction and sclerosis. Vaccine therapy. Cured.

CASE 12.—Rheumatoid arthritis diagnosed in both great toes eight years previous to examination. Acute neuritis, swelling, pain, and loss of movement in left shoulder, made worse by electrical treatment. Recurrent trigeminal neuralgia, vasomotor disturbances in fingers. Mouth: bad taste in mouth, gastric fermentation. Pus from the upper jaw, mainly incisor region, four years. Thinning and porosis of alveolus, no thickening. Vaccine therapy. Still under treatment.

CASE 13.—Attacks of acute rheumatism affecting all the joints, necessitating confinement to bed for six weeks. Treated at Woodhall Spa. All joints still creaking three years after attack. Right knee much swollen and thickened synovial membrane, patches of fibrositis in the angle of the scapula, and persistent lumbago, and pain over both sacro-iliac joints, worse at night; hands swollen and a little œdematous, swelling not confined to extensor tendons, but diffuse. Œdema of shins. Mouth: gums œdematous, spongy, bleeding. Right upper central incisor quite loose. Pus. Alveolus upper and lower jaw thickened, sclerosed. Vaccine therapy. Cured.

CASE 14.—Twenty-nine years previously puerperal septicæmia. Nineteen years later gradual development of thickening, pain, swelling, loss of movement in right knee which persisted, becoming progressively worse for the last ten years; one knee 18 inches in circumference, the other 19 inches; crepitations in both. Left wrist-joint swollen, dorsal surfaces, extensor tendons also. Mouth: no pus. Few teeth loose. Osteoporosis. Vaccine therapy. Improved.

CASE 15.—Vaso-motor disturbances with hands becoming white and cold. Rheumatic pain both shoulders. Acute attack affecting both knees, right more than left. Swelling of peri-articular tissue, crepitations in right knee, not in left; right knee remaining slightly swollen, but with little pain. Intestinal intoxication, mucous colitis. Mouth: localised area of purple and œdematous gums, principally upper jaw on left side. Four teeth discharging pus. "Gouty" teeth. Two gold crowns, which were removed, badly fitting; roots found thin and transparent. Vaccine therapy. Relieved.

CASE 16.—On March 7th, 1908, started with pain behind left ear, without obvious cause. Progressive rheumatism affecting the right shoulder and left thigh; several chills and shivering fits, followed by pain in joints, temperature in the evening going up to 100° F. Attack subsided, but the following spring another acute attack, with fever, pains in the head and neck which came on every afternoon and with any change of temperature; unable to move head. Pain in several joints, shoulder stiffness and creaking. Had a specific history, but had been treated for four years. After an X ray examination of the chest it was decided that it was possibly a case of early tubercular disease, and the patient was sent to a sanatorium, where, however, he derived no benefit. He had lost much weight, and was entirely unable to follow his profession. Subsequent history: on examination considerable amount of thickening in left shoulder-joint and in right knee, with recurring pain described as "toothache" in the neck. Hyperæsthesia over all cranial superficial nerves. Mouth: small degree of rarefying osteitis in lower jaw, rather more in upper jaw; a good deal of alveolar thickening. Vaccine therapy. Cured.

CASE 17.—First noticed stiffness in 1908, became gradually worse. No pain except in right arm. In June, 1910, unable to walk. General wasting of muscles, right knee-joint particularly fixed. Hands and feet shrunken, with acute pain in affected muscles subsequently. Worse at night. Mouth: 15 septic roots, swollen and hypertrophied gum around them, no macroscopic pus, small quantity of pus found microscopically. Considerable hypertrophy, thickening of alveolar process in upper jaw. Vaccine therapy. No improvement.

CASE 18.—Pain in both knee-joints, occurring irregularly, and worse at night. Commenced after bad attack of fever, followed by blackwater, in Nigeria. From this time gums bled; constant bad taste in mouth. Latterly pain in left tendo Achillis. Slight œdema of knees, wrists, and shins. Mouth: gums swollen, partially detached from teeth, alveolus bare in places, considerable amount of pus. Vaccine therapy. Cured.

CASE 19.—Has had rheumatic gout for the last six years; has been treated at Bath regularly twice a year. First noticed loosened teeth a year previous to the rheumatoid symptoms. A good deal of swelling and thickening in both knees, crepitations left shoulder, slight ulnar deviation in left hand. Mouth: gums purple, nodular; has acute exacerbations of pain with swelling of alveolus. No pus formation. Considerable rarefaction of alveolus in upper jaw; in lower jaw some thickening. Roots of molar teeth almost denuded of attachment. Vaccine therapy. Relieved.

CASE 20.—Recurrent shivering fits, associated with acute aching in arms and legs; both knees swollen; left hip very painful; considerable limitation of movement. Latterly attacks have been more frequent; has been treated at Bath, Marienbad, Aix, and many other watering-places. Mouth: no suppuration; strongly marked alveolar thickening in upper and lower jaws; gums pale; wasting of os marginum. Vaccine therapy. Not improved.

CASE 21.—Hyperæsthesia and recurrent pain right arm and shoulder; ulnar displacement left hand; thickening of second phalangeal joint, left ring finger. Mouth: much pain in gums; two crowned teeth, both tender. No obvious pus around gum margins. Both crowns removed. Right upper molar large cavity in bone at root; tooth much thinned and periosteum hyperæmic. Thickened and sclerosed alveolus. Vaccine therapy. Cured.

CASE 22.—Swelling and chronic pain sometimes in both knees; creaking on movement; tender on pressure. Crepitations both elbows and shoulder-joints. Frequent rashes on thighs and chest appear and disappear quickly. Tingling and loss of sensation in arms. Mouth: chronic pyorrhœa, many years' duration. Considerable alveolar thickening; much loss of bone in lower jaw.

CASE 23.—Left lower maxilla, thickening and pain following suppuration around lower molar; lower molar removed. Subsequent necrosis, followed by operation. Recurrent swelling and pain; no fluctuation; no pus. Chronic swelling temporo-maxillary joint on same side; thickening of capsule; alteration of movement. Pain worse at night. Six months after suppuration and necrosis of the jaw had acute attack of pain in right knee, which subsided, but left creaking in the joint. Vaccine therapy. Cured.

CASE 24.—Early chronic arthritis, both knees; irregular swellings affecting joints of both hands; fusiform swelling, two fingers of left hand; right index finger extensor tendons swollen, painful; unable to wear rings. Severe left-sided trigeminal neuralgia, with ptosis on same side. Mouth: considerable loosening of majority of teeth; upper centrals very loose. Much pus. Vaccine therapy. Relieved.

CASE 25.—History of gout and rheumatism for several years. Occasional attacks of pain with swelling in the knee-joints; left knee slightly enlarged. Recurrent lumbago and irregular muscular pains. Symptoms of gastro-intestinal infection; acute eczema recurrent. Mouth: gums swollen, turgid, hyperæmic. Mucous membrane covered with white flakes of desquamation. Enlargement of lymphatic glands over submaxilla. Frontal headache. Vaccine therapy. Cured.

*Group B.*

CASE 26.—Diffuse muscular pains in shoulders and arms, irregular in onset, but leaving stiffness sufficient to prevent playing tennis. Recurrent stiffness and pain in lumbar region. Pain in right gluteal region and referred down sciatic nerve. Sciatic nerve not tender at foramen. Stiffness of calf muscles. Worse at night. Mouth: one-third of teeth lost through caries. Discharge of pus lower incisor

region, and molar region upper and lower right. No hypertrophy of gum. Sclerosis of alveolus, well-marked denudation between several teeth. Vaccine therapy. Cured.

CASE 27.—Diffuse muscular pains in shoulders and back, swelling of extensor tendons of left hand. Stiffness over both knee joints. Complains of recurrent rheumatism. Trigeminal neuralgia. Mouth: all teeth removed two years previously for pyorrhœa. Thickening of lymphatic channels both sides of neck. Slight thickening of lymphatic glands of posterior cervical triangle left side. Vaccine therapy. Cured.

CASE 28.—Suffered from muscular rheumatism for six years. Recurrent neuralgias, mostly trigeminal. Stiffness and pain at back of head, recurrent but with long intervals. No focal spots of neuralgia. At Woodhall Spa six years ago, suffered from rheumatism ever since. Mouth been treated for last ten years for discharge of pus. Considerable bony deficiencies in tooth sockets with rarefaction as well as sclerosis. Vaccine therapy. No improvement.

CASE 29.—Aged 18. History of recurring attacks of fainting from no particular cause. Much acne. Irregular, diffuse, rheumatic pains, often at night, occasionally leaving stiffness of shoulders and unable to take violent exercise after. Last attack had swelling of left hand and radius. Crepitation in right knee. Mouth: discharge of pus from sockets for several years; this despite all attempts at treatment. Five tooth sockets still suppurating. Vaccine therapy. Relieved.

CASE 30.—Pain in right shoulder last three or four years; unable to put on coat comfortably; keeps him awake at night. Suffers from recurrent vaso-motor spasm of feet, with subnormal temperature. Mouth: little pus; thickened alveolus showing much loss, particularly upper jaw. Most teeth extracted, remainder one only loose. Some rarefaction; alveolus mostly thickened and sclerosed. Vaccine therapy. Cured.

CASE 31.—Pain in joints fleeting, not persistent or resulting in changes. Fermentative gastritis. Neurasthenia. Mouth: thickened and sclerosed alveolus, œdema of gums, slight pus formation. Osteoporosis in molar region of upper jaw. Vaccine therapy. Relieved.

CASE 32.—Rheumatic pains in various parts of the body with occasional swellings of joints associated with fever, disappearing after short time and not leaving any joint deformity. Swelling of hands, also disappearing and leaving no thickening. Neuritis. Acute neuralgia, trigeminal, mostly first and second divisions. Rarefying osteitis with sclerosis. Suppuration slight, but definite pus formation. Vaccine therapy. Relieved.

CASE 33.—History of occasional rheumatic pain, diffuse, not very definite. Diffuse, rarefying osteitis of alveolus, left upper jaw; central, lateral, and canine entirely denuded of bone. Much pus formation, several other teeth in upper jaw also loose. Lower gums œdematous; alveolus thickened. During course of treatment for alveolar disease sudden onset of an attack of arthritis in left knee, no fluid in joint, swelling of the internal synovial membrane and capsule, creaking on passive movement, gradually disappearing without leaving deformity of joint.

CASE 34.—Irregular rheumatism generally in shoulders, occasionally in knee-joints, no swelling, and so long as he takes plenty of exercise has no return. Constant fermentative indigestion. Mouth: for three years has had well-marked suppuration along the gum margins. Large quantity of pus now found, a good deal of alveolar infection. Vaccine therapy. Cured.

CASE 35.—Vaso-motor spasm of hands preventing writing, together with tingling and occasional burning sensation in upper arm. Recurrent stiff necks, some fibrositis in deltoids and left angle of scapula, no swelling, no definite articular lesions. Mouth: has lost all molar and bicuspid teeth from pyorrhœa. At the present time lower centrals and upper centrals standing, much coated with deposit. Discharge of pus from inflamed and hypertrophied gums. Vaccine therapy. Relieved.

CASE 36.—Bilateral enlargement of first metatarsals of both feet. Neuritis left arm; anæmic. Good deal of neurasthenia. Mouth: copious discharge of pus, much rarefaction, but with sclerosis in several situations. Vaccine therapy. Relieved.

CASE 37.—Neuritis right hand, preceded by attacks of coldness. Always suffers from rheumatism when exposed to wet. Swelling, pain, and some thickening of left temporo-maxillary articulation. Teeth nearly all loose, for eight years progressing. Pus welling from all sockets. Very great hypertrophy of gums, blue and turgid. Rarefaction of alveolus of lower teeth, so far advanced that hypodermic needle might be passed between roots of lower teeth entirely through the jaw. Vaccine therapy. Cured.

CASE 38.—Slight arthritis of shoulder on left side and left knee. Vaso-motor spasms, particularly affecting face. Acute attack of rheumatic type, followed by anginal attacks and myocarditis. Intestinal indigestion. Mouth: acute paroxysmal pain of individual teeth. Sclerosis. All extracted teeth roots transparent. No suppuration, but extracted teeth highly inflamed periosteum. Vaccine therapy. Cured.

CASE 39.—Patient aged 18 years. Acute pain, temperature 104° F. Pain in all joints, so tender could not be touched. Quite well in a fortnight. For two years had alternations of general rheumatic pains with attacks in feet, hands, shoulders, or knee. Frequently attack in big toe. Harrogate, Marienbad, Buxton. Mouth: much hyperæmia of gum margin, particularly anterior portion of mouth. No pus. Rarefaction of alveolus. Vaccine therapy. Relieved.

CASE 40. Occasional rheumatic pains, no definite joint lesions. Mouth: has lost nearly all teeth from loosening. Has had acute exacerbations with pus formation in mouth after last three confinements. Two children both suffered from rheumatic fever. Vaccine therapy. Relieved.

CASE 41.—Had acute endocarditis when two years and three months old. Five to six months after brother had had similar disease with high temperature and heart infection. First attack corresponded to time his mother was suffering from acute pyorrhœa. Recurrrent attacks, fleeting pain in joints, præcordial pain, breathless. Mouth: present condition gingivitis with marked suppuration around several temporary teeth, mucosa of mouth generally inflamed. Vaccine therapy. Cured.

*Group C.*

CASE 42.—Patient aged 18 years. Irregular trigeminal neuralgia. Stiffness and pain left temporo-maxillary joint. Muscular cramps, irregular, at night on three occasions. Mouth: diffuse gingivitis with hypertrophy of gum. All teeth much discharge of pus. Trouble commencing after acute attack of measles. Vaccine therapy. Cured.

CASE 43.—Subsequent to an attack of influenza suffered from palpitation and diffuse muscular pains, aching in joints which persisted for six months. Temperature of 101° F. at intervals at night, lasting three or four months. Occasionally swelling and stiffness in hands and feet; right hand goes to sleep at times. Heart ringing first sound, slight roughness. Hæmoglobin 75 per cent. Mouth: has had bad taste in mouth ever since influenza, and has noticed recession, bleeding, and discharge from the gums. Well-marked infection of the alveolus in many situations. Few teeth loose. Vaccine therapy. Relieved.

CASE 44.—Recurrent attacks of sacro-iliac neuralgia, followed by stiffness in lumbar region. No history of generalised rheumatism. Mouth: lower central incisors loose, discharge of pus from upper and lower gums. Rarefaction of bone. Vaccine therapy. Cured.

CASE 45.—Patient aged 50 years. Recurrent attacks of asthma since 35 years of age. Attacks of colitis. Various operations for nasal polypi suppuration. Last four years emphysema, with occasional attacks of bronchitis. Recurrent lumbago. Intestinal indigestion. Occasional swelling of tendons of back of hand. Recurrent stiff neck. Mouth: takes great care. Little or no pus found, but well-marked interstitial deficiencies, thinning of bone, sclerosis of alveolus. Vaccine therapy. Relieved.

CASE 46.—Attacks of unaccountable sleeplessness, with sudden loss of sensation and feeling in one arm. Rheumatism which interferes with his golf. Mouth: suppuration acute left upper canine, most teeth lost through pyorrhœa, much shrinkage of alveolus, except where teeth are standing, where, particularly in the upper jaw, considerable thickening has taken place. Vaccine therapy. Cured.

CASE 47.—Irregular attacks of stiffness and pain in knees and right hip. Dyspepsia, three years' history. Mouth: acute suppuration in mouth. All teeth affected, gums swollen, œdematous, much wasting of alveolus, little or no thickening. Vaccine therapy. Cured.

CASE 48.—History of mild polyarthritis, many years' standing. At times knee-joint becomes swollen and tender; slight thickening right knee, some loss of movement. Mouth: much alveolar thickening, left side of upper jaw being at least twice the normal size. Suppuration around roots of upper molar teeth, much elongated. Rarefaction of bone around teeth. Vaccine therapy. Cured.

CASE 49.—Last three or four years has had irregular attacks of lumbago, with rheumatic pain in shoulders and down right arm. Occasionally swelling of fingers of right hand; no permanent enlargement of joints, but sometimes definite swelling which makes it difficult to wear her rings. Mouth: mouth and gums normal, with exception of right upper bicuspid tooth, which is dead, and from which a chronic sinus has existed for the last six years. Alveolus around this bicuspid tooth is thinned and almost entirely removed. Some deeper infection into the body of the jaw. Antrum not affected.

For the sake of brevity the section dealing with the bacteriology of the mouth is confined to the consideration of those cases in which animal experiments have been made. Animal experiments were made in respect of 17 of the cases: 8 in Group A, Nos. 2, 4, 14, 16, 17, 21, 24, and 25; 7 in Group B, Nos. 31, 32, 34, 35, 36, 38, and 40; 2 in Group C, Nos. 44 and 49. In all the 49 cases a bacteriological investigation was made and organisms similar in general characters to those described in Table II. were isolated. In addition to these cases giving a definite history, 12 non-rheumatic cases of rarefying alveolar osteitis were submitted to bacteriological examination, the streptobacillus isolated from them and used for animal experiments. The organisms obtained resembled those from the rheumatoid cases. The two groups of cases are indicated in Table III., cases from 50 onwards being those in which no rheumatic symptoms were observable. The bacteria isolated from the cases which were not suffering from arthritis or other rheumatic symptoms in several instances caused swellings and progressive changes when inoculated into the knee-joints of rabbits. I have also isolated the streptobacillus from cases of posterior rhinitis, chronic pharyngitis, quinsy, and disease of the antrum of Highmore. I have also isolated the streptobacillus from the urine of four cases in which it was present in the mouth. In my last 100 cases of mouth diseases examined bacteriologically of all varieties excepting dental caries I have met with it 65 times.

It will be seen from the notes of many of my cases that a considerable amount of crown and bridge work had been inserted in the unfortunate persons' mouths, and I cannot express too great a horror of that potent predisposing cause of infection of the jaws—namely, the ill-fitting, ill-adjusted, ill-conceived, and pernicious cap crown. To the objector who demurs to this condemnation I would only retort that it is a device which separates the normal gum edge from its attachment to the tooth, that rarely, if ever, fits closely to the contour of its encircled victim, but invariably projects in such a manner that débris of food is trapped under its rim and inevitably promotes ulceration, periosteal infection, and, sooner or later, rarefying osteitis and suppuration.

## TREATMENT.

The first suggestion that treatment of the mouth infection might also influence the arthritis was given by a case whose mouth was resplendent with gold crowns, Case No. 6. A bacteriological examination was made, the infecting organisms isolated, and an autogenous vaccine prepared.

Preliminary inoculations were given and all the worst and badly infected teeth removed. The vaccine was then given regularly, first at periods of ten days, then at fortnightly intervals for six months, and after that at intervals of six weeks for a year. The first inoculations were associated with exacerbation of the joint symptoms. The patient made a slow but steady recovery. The left knee-joint, which had undergone some bony change, has remained permanently thickened, particularly the outer margin of the head of the tibia, but the thickening of the tendon sheaths of the hands has disappeared, together with the joint swelling; the patient is able to walk without pain, and has so far recovered the use of his limbs that he was able so long ago as last September to mow his own grass plot. He has gained about 2 stones in weight, and has been able to return to his occupation. Four fresh vaccines were made during the period of treatment; the dose to commence with was 10,000,000, but the later doses were 150,000,000 to 200,000,000, on each occasion being the streptobacillus described above, the organism in this case being Nos. 125B and 237B on the list in Table II. The line of treatment of this case is that adopted as general routine. In nearly all of my early cases distinct increase of the arthritic pain and swelling was caused by the first inoculation; latterly the preliminary dose has been reduced to avoid this exacerbation.

Case No. 16 was another of the earlier cases, but in this instance the organisms were tested on mice, mainly for virulence, no intravenous or other inoculation having been made into rabbits; in fact, it was not until May of last year that I commenced direct inoculation into the knee-joints of animals. It will be seen on reference to this case that the amount of inflammation in the mouth itself was practically *nil*. The patient had, however, lost a number of his teeth, and those which remained showed a small but definite amount of rarefying osteitis in the lower jaw. There was also a considerable amount of alveolar thickening. There were no other obvious sources of infection, although careful search was made of all the orifices, and the bacteria were isolated and tested against the patient's blood. Resource was therefore had to immunisation by means of a vaccine prepared from the patient's mouth. Almost from the first inoculation a diminution took place in the slight degree of fever from which the patient constantly suffered, the temperature generally being raised to 100° at night. The inoculations were carried out regularly and progressive improvement took place. The specific treatment was also continued, as at one time some parietal thickening occurred which was thought to be of specific origin. The patient made a gradual but complete recovery, having lost all stiffness, all neuralgia, and, having regained his normal weight, has been enabled to return to his business; more important still, he is now able to play golf again without difficulty. The two mice inoculated with the patient's organisms recovered without any ill effects.

Case No. 3 was another in which a very slight amount of mouth infection was to be found. She had a history of indigestion, her throat was hyperæmic, there was occasional pain in the mouth and palate, and the latter showed slight ulceration behind the central upper incisors. There was slight but definite infection of the alveolar process, but without very careful examination this could not be detected, as to all appearances the patient's teeth and gums were normal; on careful examination with a thin platinum probe it was found that here and there the gums were detached and distinct loss of alveolar process in the interdental position had occurred. The streptobacillus was isolated from this patient, who received injections at weekly intervals, and latterly at more extended periods. At the first three injections increase of pain and swelling of the affected parts occurred. She was under treatment from May, 1910, to December of the same year. By this time all the swelling in the knee had entirely disappeared, the joint was quite normal, the patient had discarded not only her crutches and her stick, but was able to dance.

Case No. 23 is of interest because it was the only one in the whole series of 49 cases in which there was any suggestion of infection either in or in the neighbourhood of the temporo-maxillary articulation, and in this case the organisms found differed from those obtained from the majority of the cases. The organism from this case belonged to the type given at the head of Table II. in that the organisms produced no fermentation of carbohydrate. The swelling entirely disappeared after eight inoculations and has not returned.

Forty-five out of the 49 cases were treated with autogenous vaccines of the streptobacillus malæ, 21 in Group A, 16 in Group B, and 8 in Group C. Of these cases 23 have been cured, inasmuch as their arthritic symptoms have resolved sufficiently for them to go about their normal avocations; of these, 11 belonged to Group A, 7 to Group B, and 14 to Group C. Four cases in Group A and 1 in Group C refused treatment, and of the remaining cases 8 in Group A are still under treatment, 4 have shown marked improvement, and in 4 so far no improvement appears to have taken place, whilst 2 cases ceased treatment after a couple of months, having been in no way benefited, but in no case was the condition in any way aggravated. In Group B 7 cases are still under treatment and 2 were in no way benefited. In Group C 4 cases have been cured and the remainder are still under treatment.

TABLE IV.

| Cases treated. | Results of treatment. | | | |
|---|---|---|---|---|
| | Cured. | Relieved. | Still under treatment. | Not improved. |
| 45 | 23 | 14 | 6 | 4 |
| Group A, 21. | 11 | 7 | 4 | 2 |
| Group B, 16. | 7 | 7 | 2 | 2 |
| Group C, 8. | 5 | 3 | — | — |

The routine method of treatment which I have adopted in all these cases has been inoculation with autogenous streptobacillary vaccines, followed by attention to the local mouth infection. Where extraction was deemed necessary, and the question of extraction has generally been decided with the assistance of X ray photographs, preliminary immunisation of two or three doses of vaccine has always been undertaken before the removal of the infected tooth. I am of opinion that harm may result from the free removal of even loose teeth in sufferers from arthritis deformans unless preliminary treatment is adopted, and I have found, as a matter of practice, that increased local swelling and pain does occur in many instances in arthritis deformans after the removal of teeth, and may even follow an ordinary process of scaling tartar-coated teeth.

In conclusion, it must be understood that my contribution to the study of arthritis deformans coincident with alveolar osteitis does not seek to establish a specific organism as the etiological factor in *all* cases of rheumatoid arthritis, infective fibrositis, muscular rheumatism, &c., but that in diseases of the jaws, especially rarefying alveolar osteitis, a streptobacillus is present, pure cultivations of which inoculated into or around the knee-joints of rabbits have produced symptoms similar to and indistinguishable from arthritis deformans; that in such disease of the mouth and jaws the treatment of the disease locally and by means of autogenous vaccine prepared from the streptobacillus has been associated with amelioration and disappearance of the arthritic symptoms in a greater number of instances than can be ascribed to fortuitous coincidence.

A BRIGHTON WORKHOUSE SCHEME. — The Brighton board of guardians at its last meeting agreed in principle to the complete separation of the infirmary inmates from the workhouse inmates, a separation to be effected by the elimination of all the children from the workhouse and accommodating them at Warren Farm School, which is also under the jurisdiction of the guardians. This removal would provide the accommodation needed at that institution for the classification of the sick. The daily average number of inmates of the workhouse is 1350, of which number about 500 are maintained in the infirmary. The nursing staff numbers 40, comprising a superintendent-nurse, a night sister, 10 charge nurses, 11 staff nurses, 15 probationers, and 2 male nurses. The guardians were almost unanimous on the matter, 23 voting for the scheme and only 1 against. The vote was an endorsement of the view taken by the committee which considered the question that "in all probability the time is not far distant when Poor-law infirmaries of the size of that of Brighton will be under separate administration from the workhouse."

ABSTRACT OF

# The Lettsomian Lectures

ON

# OPERATIONS FOR STONE IN THE MALE BLADDER.

*Delivered before the Medical Society of London on Feb. 6th and 20th and March 6th, 1911,*

BY WILLIAM F. HASLAM, M.B. BIRM., F.R.C.S. ENG.,

SURGEON TO THE BIRMINGHAM GENERAL HOSPITAL.

## LECTURE III.[1]

*Delivered on March 6th.*

Mr. Haslam said that an attempt was made by Deschamps in 1796 to revive the Marian operation on modified lines by what he termed a "mixed method." This resembled the lateral operation in the external incisions and the Marian in dilatation of the prostate and neck of the bladder, and he says, "who knows but at some future time surgeons may not be tempted to return to this method?" In 1819 Sir Astley Cooper extracted a stone as large as a walnut by this mixed method; in 1830 it was advocated by Dr. Buchanan of Glasgow, and in 1842 it was again brought forward by Dr. Willis. It received the name of "lithectasy" and then was heard of no more. By this time the lateral operation was becoming firmly established, and in 1853 Coulson says: "The lateral operation is now universally adopted, not only in this but in all other countries, and hence we have *primâ facie* reason for concluding that as a general method it is the best." The rectangular staff of Buchanan was by some preferred to the ordinary curved staff as facilitating the opening of the urethra and the passage of the knife through the prostate, but this in no way modified the steps of the lateral operation nor was it at all widely used. The first idea of the bilateral operation appears to have been due to Le Dran, who, in performing the lateral operation, sometimes found his internal incision was not sufficiently free. He therefore divided the right side of the prostate as well as the left. Sir Astley Cooper and others adopted the same practice. These operations, however, resembled the bilateral method only so far as the double incision of the prostate. The bilateral operation as a definite procedure was finally established by Dupuytren in 1824, and was described by William Coulson in his work on lithotrity and lithotomy published in 1853. The quadrilateral method of M. Vidal de Casis was proposed in 1828. The first transverse incision was made as by Dupuytren, and then the prostate was divided in four directions, but the operation was never taken up. In 1824 Aston Key of Guy's Hospital published a short treatise on the section of the prostate gland in lithotomy with a safe and easy method of conducting the operation on the principles of Cheselden. He designed the staff to obviate the dangers attending the use of the gorget, and at the same time to adhere closely to the principles laid down by Cheselden in his second operation. The recto-vesical operation is said to have been performed by the Egyptian lithotomists from time immemorial, and was written about in the sixteenth century by a writer under the assumed name of Vegetius. It was described by Hoffmann in 1779 and by Martin in 1817. M. Sanson brought it before the notice of the profession in France in 1817. Sanson, however, soon gave up this method, and substituted for it the one practised by Vacca. The median operation was to some extent a modification of the Marian. A keen advocate of the median operation in this country was Allarton, who in 1854 published a work dealing with it under the title of "Lithotomy Simplified."

Concerning lithotrity the lecturer said that the occasional passage of a stone by the urethra must have suggested to the careful observer the possibility of dilating the urethra so as to facilitate the passage of a small stone, or to enable one to be seized with a suitable instrument and drawn through the urethra, or of being able to break up a stone, already too large to pass, into small fragments which could be voided with the urine. Indeed, the breaking of a large stone had been practised from time to time for many centuries, when it was found to be impossible to extract it through the incision made in the Celsian operation. The Egyptians practised the removal of small stones by dilating the urethra, and the same method was adopted by the Arabians. In THE LANCET for 1835, in the number for May 2nd, the position is summed up as follows: "So far as our own observations and inquiries have extended, we are inclined to believe that if lithotrity were to be taught generally in the schools, and brought into ordinary use amongst practitioners, the cutting operation for stone would in a few years become obsolete; because the facility with which small stones could be crushed, would leave no large calculi to require the use of the knife." No great advance was made until 1878, when Bigelow of Boston showed that it was possible to break up a stone so completely at one operation that all the fragments could be washed out through a large evacuator. With the establishment of Bigelow's operation surgeons were better enabled to consider the possibility of dealing with larger stones by crushing than was formerly the case. In skilled hands and with suitable instruments the operation is well adapted for almost any stone that may be met with. It is probable that lithotrity will never be so generally adopted in this country as in those where stone is common. There is no doubt that here the suprapubic operation is on the whole preferable. The operation of perineal lithotrity was first performed as a definite procedure by Dolbeau, a French surgeon, in 1862, and some years later was reintroduced by Mr. Reginald Harrison.

In order to ascertain what operations surgeons were performing for vesical calculus in this country certain questions were sent to surgeons attached to the larger hospitals. To the first question, What operation do you usually perform on the removal of a stone before the age of puberty?—there were 221 replies. From an analysis of these figures it is clear that the suprapublic operation is the one usually performed. Seven only refer to lithotrity as the method adopted, without any reference to the size of the stone or other circumstances. The others who perform lithotrity do so only after making choice of such cases as seem suitable, in their opinion, for the operation. The lateral operation as well as the median are still mentioned, though apparently are very seldom performed. To the second question, What operation do you usually perform for the removal of a stone from the male bladder after puberty when there is no evidence of prostatic enlargement?—there were 240 replies. These returns show that surgeons are prepared to consider the advisability of performing lithotrity in the adult more frequently than in boys, but the number of those who practise the suprapubic operation is in excess of those who use lithotrity, and it should be noted that of these a large number reserve it for small stones, doing the suprapubic operation for large ones. The third question, as to the treatment of stone when there is evidence of prostatic enlargement, elicited 224 replies as follows: For the treatment of stone in the presence of an enlarged prostate the suprapubic operation is, from these returns, the method adopted by almost all surgeons, only 16 out of 224 being prepared to discuss the desirability of attempting lithotrity under these conditions. The fourth question dealt with the treatment of the wound in cases of suprapubic lithotomy. There were 230 replies. The chief point of interest in this question is as to suture of the bladder and of the abdominal wall, and whether a drain is used or not. It is evident that there are few surgeons who venture to sew up the bladder and close the abdominal wound without some form of drainage, though there are many who will close the bladder and use a drain to it; while rather more than half the number prefer to use either partial suture or none at all. Such is the condition of practice for stone in this country at the present time, and though it is always uncertain what changes may take place in the future, it does not seem probable that there will be any great alteration in the immediate future. No doubt, under modern conditions, the lateral operation would yield good results so far as the mortality of the operation is concerned, if done by surgeons who had fairly frequent opportunities of performing it. But, in addition to those dangers which might be avoided by a skilled operator, there is the possible injury to the ejaculatory ducts, and consequent sterility, which is

[1] Abstracts of Lectures I. and II. were published in THE LANCET of Feb. 18th (p. 423) and 25th (p. 491), 1911, respectively.

beyond the control of the surgeon. There does not seem to be any real effort at the present time to displace the suprapubic operation by crushing, nor does it seem likely that any great improvement can be made in the details of the former, so that we may fairly regard the mode of treatment of to-day as likely to continue for some time.

# THE PRINCIPLES ON WHICH THE TREATMENT OF RESTING CONDITIONS OF THE SKELETON IS BASED.

BY W. ARBUTHNOT LANE, M.S. LOND., F.R.C.S. ENG.,

SURGEON TO GUY'S HOSPITAL; SENIOR SURGEON TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, W.C.

IN 1886 I published in the Guy's Hospital Reports[1] a study of the causation of the deformities which develop in young life and attempted to place the treatment of these conditions upon some definite scientific basis. As more than 25 years have elapsed since I wrote that paper, which dealt very fully with the subject, I think it may be of some interest if I consider what changes have taken place in the interval. I purpose quoting from the commencement of that communication to show that the position as regards these deformities does not materially differ now from what it was then:—

> I propose to discuss the several deformities which arise during childhood, and I will attempt to consider more particularly their causation and pathology, for, after we have obtained a thoroughly clear idea of the manner in which such abnormal conditions are produced, and the relative importance of the several factors which may combine to determine their formation, we shall be able to compare the advantages presented by each of the many modes of treatment which have been suggested or practised by different surgeons, and to draw our own conclusions upon their relative merits. I hope to be able to throw some new light upon the manner in which many of these deformities arise, and will attempt to explain their causation upon a more scientific basis than that which is at present described in the works which I have read upon the subject.
>
> Anyone who has patiently and thoughtfully plodded through much of the abundant literature on deformities cannot but be struck by the small proportion which the consideration of the causation and pathology of these conditions bears to that of the special form of treatment recommended. Perhaps much of this is due to the fact that to a very considerable extent the treatment of deformities has fallen into the hands of mechanicians, who are not guided in their practice by a very intimate knowledge of the several factors which determine the development and progress of these conditions and of the pathological changes which they present, but they are imbued rather with the idea that each deformity can only be treated by the application of some particular instrument or apparatus. I do not for a moment wish to depreciate the value of instrumental aid or of the assistance which a skilful mechanician can afford us; I wish rather to indicate that there are other factors which we cannot meet solely by the application of mechanical supports, and that in many cases we may, by relying too much upon appliances, aggravate instead of control the condition and progress of the deformity.
>
> The tendency of the present day is to specialise and remove the subject of the treatment of deformities from the realm of general surgery rather than to elaborate our knowledge of the causation and pathology of deformities generally, and then to classify these facts under several heads and obtain from them general indications as to our treatment of them. There is also a strong inclination to account for the development of each deformity on some peculiar ground special to itself rather than to suppose that deformities acquired during growing life are due to the same causes modified by secondary circumstances, such as variations in the character of different joints as regards the mode of transmission of superjacent pressure, &c.
>
> We find very eminent surgeons of world-wide reputation developing theories as to the mode of causation of the same deformity, which are often so completely contradictory that if one be true the other is necessarily false Yet each of these surgeons formulates a mechanical treatment based upon his theory, so that, if these treatments bear out the intentions of these surgeons, they must of necessity be also contradictory in their results.
>
> In this branch of surgery, more frequently, perhaps, than in any other, the surgical pathologist has but too frequently mistaken the cause for the effect. Surgery differs from medicine in the following important particular. In the former a false hypothesis or theory frequently suggests a course of treatment based upon it, which may not only be not beneficial, but absolutely prejudicial to the patient, while in the latter the treatment carried out is usually quite independent of the almost innumerable theories of causation which are invented about every obscure medical disease. As an instance of this, take the disease diabetes. Therefore, it is of much importance, as regards treatment, that we should obtain as thorough and as complete a knowledge as possible of the factors which determine the development and progress of deformities, and of the influence exerted by each.

The only important thing I have learnt since I wrote that paper is that respiratory incapacity, as I termed it, or, in other words, an oxygenation of the blood sufficiently defective to prevent the individual from leading a vigorous active life, is not, as I believed then, the primary factor, since this defect in oxygenation is itself consequent on intestinal stasis.

By intestinal stasis I mean such a delay of the contents of the intestines in some portion of the gastro-intestinal tract, but more particularly in the large bowel, as allows of the absorption into the circulation of a larger quantity of toxic material than can be dealt with effectually. This delay results from a mechanical alteration in the normal arrangement of the drainage apparatus. In early life it is produced by an abnormal distension of the intestines consequent on too frequent feeding or by the use of articles of an unsuitable nature. Later it is brought about and accentuated by the erect posture of the trunk which is assumed from the time of getting up until going to bed.

Dr. Vaughan and Miss Wheeler have shown[2] that proteids can be split into a poisonous and non-poisonous portion, and that the deleterious component is a respiratory poison. It can produce acute, subacute, or chronic poisoning depending on the manner and rate of its introduction into the body. They also showed that animal albumin is more poisonous than vegetable albumin. It is upon this fact that the advantages of a vegetarian diet depend, while it also throws much light on what is called "dieting" by the physician and which has been arrived at somewhat empirically.

I would also call attention to some elaborate experiments performed by Dr. Turck of Chicago which bear in a very important manner upon intestinal stasis and consequent auto-intoxication. I have discussed this question fully in several papers.[3] The views of the profession have changed very rapidly on the importance of the subject of intestinal auto-intoxication produced by intestinal stasis since the discussion on constipation which took place at the meeting of the British Medical Association in London in July, 1910, which was so ably opened by Dr. J. F. Goodhart. It had become the fashion of the physician to cast ridicule on the influence exerted by intestinal auto-intoxication upon the individual, and that was the attitude of the opener of the debate and of the majority of the physicians who took part in it. Since that discussion, however, the views of the profession generally have undergone an abrupt change, and the recognition of the enormous influence for evil of intestinal stasis is beginning to impress itself upon their minds. I have introduced the subject here, as I wish to point out most clearly that the primary factor in the development of resting deformities, including the deformities of rickets, is auto-intoxication consequent upon an intestinal stasis, and that the respiratory incapacity which I originally regarded as the primary factor is merely a secondary one, but directly consequent on intestinal auto-intoxication. It is therefore the duty of the medical attendant in a case of resting deformity to deal effectually with the primary factor in the development of the trouble, having rendered himself thoroughly familiar with the symptoms that intestinal auto-intoxication produces in different individuals.

Before going into any detail I would put forward the following general principles which I have formulated and which bear upon the subject.

1. The skeleton represents the crystallisation of lines of force which when transmitted in one direction are laid down as compact tissue, when transmitted in varying directions as cancellous tissue. The arrangement of the cancelli is such as to transmit force applied in different directions to the best possible advantage. Any interference with the form of the skeleton, as by a fracture of a long bone, is followed by an attempt to lay down anew the lines of force, and in the very young subject the recrystallisation is complete, the old shaft being removed and replaced. The older the subject the more is this change limited to the locality of the fracture and the less complete is the restoration.

2. The rates of bone formation in the several portions of growing bones vary inversely as the amount of pressure sustained by them. A subnormal pressure means an abnormal amount of bone formation, while the exercise of a pressure in

Nisbet and Co., 1910, &c.

excess of the normal results in the formation of a subnormal amount of bone.

In the child whose nutrition has been impaired by intestinal stasis and consequent auto-intoxication the amount of nutrition sufficient to produce normal bone is in abeyance. Consequently the bone is of subnormal density, while the periosteum and growing lines are abnormally active. The growing lines react much more markedly to pressure than do those of the normal subject. When this condition of the osseous system becomes a conspicuous feature it is called rickets.

In order that the skeleton shall remain normal it is necessary that it should perform certain attitudes of activity and certain attitudes of rest. For each joint, as for the body generally, there is an attitude of activity and an attitude of rest. The habitual assumption of an attitude of activity results in the first instance in the fixation of that attitude and later in its exaggeration. This can be demonstrated by an examination of the skeleton and soft parts of a man who has for many years been engaged in any laborious pursuit. I cannot illustrate this more clearly to you than by calling attention to the anatomy and physiology of the coal-trimmer and shoemaker, regarding which I published papers in 1887 and in 1888 respectively.[4] Those papers, with others dealing with the anatomy of other varieties of labourers, attracted a certain amount of interest at the time they were published, since they demonstrated evolution in a portion of a single lifetime. The several changes which the body underwent in these labourers were in response to these separate principles—namely: 1. Strain[5] tends to produce ossification along the direction in which it is exerted. 2. Pressure tends to produce destruction of the soft structures intervening between bones and definite changes in the form and density of bones. 3. Whenever it is to the advantage of the individual that an entirely new mechanism should develop independently of the exercise of pressure or strain such a formation tends to arise. In other words, the anatomy of the individual varies with his mechanical relationship to his surroundings.

All the changes which arise in the direction of the fixation and exaggeration of definite attitudes or sequences of attitudes of activity are with the view of reducing to a minimum the expenditure of nerve and muscle energy, and nothing is more striking than this economy as it is manifested by the labourer. Whereas in the adult labourer all the energy is devoted to the performance of a certain movement or sequence of movements in the most economical manner possible, so in the growing child whose store of energy is damped down and reduced by the presence of noxious material attitudes of activity are avoided, and instead the child assumes habitually attitudes of rest. These attitudes in the child, like those of activity in the adult, become fixed and later exaggerated. In the child besides the three laws already considered we have the changes which result from pressure or strain upon the growing lines, and these, again, are still further exaggerated in the imperfectly nourished thick growing lines of the so-called rachitic child. In them also the shafts of the long bones especially may bend for the same reason.

The most conspicuous feature in the child affected by intestinal auto-intoxication is the very defective manner in which the respiratory function is carried on. Since thoracic respiration demands a much greater expenditure of energy than does the diaphragmatic variety, the former is very distinctly in abeyance, and respiration is carried on rather rapidly and superficially by the diaphragm and abdominal muscles. The thorax is retained in a position of complete expiration. This attitude, which forms part of what I have called the symmetrical attitude of rest of the trunk, and is termed by the profession dorsal excurvation and by the public round shoulders, can be studied together with the several tendencies to change in a vertical antero-posterior section of a feeble old person in whom, for the same reason, respiration is carried on solely by the diaphragm. In this position the spine forms exaggerated curves in an antero-posterior plane and the length of the whole column is at its shortest. Should the same child assume habitually the normal asymmetrical attitude of rest of the body such as exists when "standing at ease," the pelvis is rotated around an antero-posterior axis, and the superjacent vertebræ deviate from the middle line so as to form curves in a transverse plane, each vertebra rotating around an oblique axis made up partly by the assumption of the asymmetrical attitude of rest of the trunk and partly by the inequality of the length of the lateral supports of the trunk. From the habitual assumption of this attitude to the exclusion of the corresponding attitudes of activity the typical scoliosis or lateral curvature of the spine results. From the type that arises in this manner there are variations owing to the varying factors or positions that may incline the pelvis, as riding on a side saddle, faulty sedentary attitude, &c.

Knock-knee results from the habitual assumption of the attitude of rest of the knee-joint. In this position the superjacent weight is transmitted through the knee-joint in such a manner that the anterior and outer quadrant of the epiphyseal line transmits an abormally great amount of weight, while the posterior and inner quadrant sustains a pressure less than normal. In consequence the external femoro-tibial angle becomes reduced, as also does the anterior femoro-tibial angle. The latter may be very marked when the backward displacement of the knee-joint is referred to as "back knee." These epiphyseal changes are exaggerated in the condition of auto-intoxication called rickets, in which the displacement of the knee is still further increased by the bowing of the shafts of the long bones in a plane which runs from before backwards and inwards.

Flat-foot is due to the habitual assumption of the attitude of rest of the foot, which later becomes fixed and then exaggerated. The position of rest of the foot is one of abduction, while that of activity is one of adduction. The coal-heaver who carries habitually a heavy load on his back has his foot fixed in the position of activity or of adduction. Similarly the child whose activity is depressed by a varying degree of auto-intoxication assumes the resting posture constantly and the condition develops.

When I first described the causation, &c., of flat-foot it was regarded as being due to the yielding of an elastic inferior calcaneo-scaphoid ligament. I was able to demonstrate that this was a totally wrong conception, and that the anatomy and physiology of the foot was quite different from that described in the text-books of surgery and anatomy. I am sorry to say that both surgeons and anatomists move slowly, and that they appear to have failed to grasp the importance of this subject. I do not propose discussing the details here, as I have nothing to add to that paper which is now a quarter of a century old.

I have here merely considered the general principles which must influence the surgeon in his treatment of the condition. The details of treatment follow naturally on those lines.

# THE EDUCATION OF THE DEAF:

## ITS PRESENT STATE IN ENGLAND, WITH SUGGESTIONS AS TO ITS FUTURE MODIFICATIONS AND DEVELOPMENT.

BY MACLEOD YEARSLEY, F.R.C.S. ENG.,

SENIOR SURGEON TO THE ROYAL EAR HOSPITAL; MEDICAL INSPECTOR OF LONDON COUNTY COUNCIL DEAF SCHOOLS; LECTURER TO THE LONDON TRAINING COLLEGES FOR TEACHERS OF THE DEAF; EXAMINER TO THE JOINT EXAMINATION BOARD FOR TEACHERS OF THE DEAF, ETC.

### III.[1]—THE AGE AT WHICH EDUCATION SHOULD COMMENCE. THE APPLICATION OF EUGENICS TO DEAF-MUTISM.

IN this, the concluding article, I shall deal with the second need postulated in the introduction, "the education of the congenitally deaf and of those very deaf children who, by reason of the early age at which they acquired their deafness, have not developed speech, to be commenced at a much earlier age than is now the general rule, in order to give them that physiological, in contradistinction to pedagogical, training to which they have as much right as the normal hearing child."

As in discussing classification, so I shall first review very

[1] Articles I. and II. were published in THE LANCET of Feb 25th (p. 495) and March 4th (p. 574) respectively.

briefly the courses followed in different countries, and, in comparing the education of the normal with the deaf child, offer certain observations which seem to me to give strong physiological reasons for commencing the education of the very deaf at a much earlier age than has hitherto been considered advisable, using the term "education" in its physiological rather than in its pedagogical sense.

According to Bélanger[2] it appears that in France the age of admission to the schools varies considerably, and the general tendency is to reduce it. Although some pupils commence at six years, and sometimes earlier, circumstances seldom allow them to enter the schools before 11 or 12 years of age.

In Italy the want of legislation appears to make the age of entry, into the few charitable schools for the deaf that exist, uncertain.

In Germany the children attend compulsorily from the age of 6 to 14 years. In Denmark instruction commences at 8 years; in Holland at about 7 years, under certain circumstances even a little earlier.

In the British Islands the majority of children commence at about 7 years, but in some schools they are received at 5 years. In England it is compulsory that all deaf children should begin their education at 7 years of age, but a Government grant can be obtained for them if they enter at 5 years. In the Irish schools mentioned in the first article the general age of admission appears to be 8 years.

In the United States, as was the case with classification, a somewhat better condition of things exists. Few schools, it is true, receive children earlier than seven years of age, but there are pupils in the Pennsylvania Institution for the Deaf and Dumb one year younger. There is, however, a tendency in America, not only to keep the deaf child at school later in life, but—and this is of great importance—to take him in hand very early. This is done at Boston, under Miss Fuller; at Chicago, under Miss McCowan; and at Bala (near Philadelphia), under Miss Garrett. The last-named institution, taking children at 4, 3, or even 2 years, claims that they can enter ordinary hearing schools six or eight years later. The tenth report of this "Home for the Training in Speech of Deaf Children before they are of School Age" for 1910 states that the aim of its trustees is "to surround young deaf children with the same uninterrupted condition for acquiring articulate speech and language with which all hearing children are surrounded, the difference being that sight instead of hearing is the medium used. The use of either natural signs, arbitrary signs, or the manual alphabet is strictly prohibited." It now contains 65 children, and the success of this excellent institution is undoubtedly very great. It is well spoken of by Dr. Kerr Love and Mr. F. G. Barnes, both of whom have visited it, although I understand that both these gentlemen doubt the wisdom of passing on such seriously handicapped children to ordinary hearing schools.

I have no desire to express any opinion as to the wisdom of taking children early for oral training with the intention of transferring them later to hearing schools, because I have no practical knowledge thereof, and do not care to form any judgment thereon from printed reports or from hearsay evidence. But I do believe that the practice, which appears universal, of making no effort for compulsory oral training before six years or even later, is a grave mistake, and a potent cause of failure in the oral training of the deaf.

This view I shall endeavour to substantiate to the best of my ability, and, to do so, the physiological education of the normal must be compared with that of the deaf child. The development of speech has been admirably described by Dr. John Wyllie,[3] whose dissertation should be read by every person interested in the matter, and especially by every teacher and every parent, actual or expectant, and to whom I would refer the reader for details. By the end of the second year of his age a normal-hearing child has already some understanding of words spoken, together with a vocabulary of words of his own invention and a limited production of intelligent speech. He is able to say short baby sentences of two or three words. Between the ages of two and seven the hearing child is rapidly developing, whilst his unfortunate deaf brother is at a standstill. The former is receiving items of education every minute of his waking life, through the channels afforded by his organs of hearing, so that not only are speech and language being continuously impressed upon his cerebral cortical centres, but they are, by ceaseless reiteration, becoming stored up both as sensory and motor memories. This ceaseless reiteration is a highly important factor, for it goes to make speech perception and speech production automatic, and is practically absent in the deaf child. By this constant repetition, and by the intimate relation between the language-appreciating centres and the language-producing centres speech becomes automatic before the education begins of those centres which are concerned with writing and more difficult language training, centres which are of later development in the history of the race than are those of mere speech, and are preceded in the normal child by a pre-speech era of gesture language. It is a well-known axiom that as the pre-natal development of the child is an epitome of the phases of his evolution from the unicellular ancestor, so is his post-natal development an epitome of the evolution of his race from barbarous savage to civilised man. Gesture, sign language, inarticulate vocal cries, and the crude and poorly developed thought which accompanies those simple attempts at expression are all seen in the normal child until he attains to primitive and later to more perfected speech—"the silver bridge over which the thought of man has come to travel."[4] It is this pre-speech era of gesture language which becomes more fixed (probably because it is older in the racial history and, therefore, more easily used) in the deaf child to the detriment of oral training, and it is for this reason, joined to his strong faculty of imitation, that deaf children are so prone to revert to signs if allowed to associate with oral failures. The fact of automatic speech is of enormous importance to the normal child, especially because it commences to develop early, and I believe that by training the speech centres in the deaf at an earlier age we might help them at least to approach the automatism of speech of the hearing child.

The inestimable value of hearing in the physiological education of the speech-centres in the normal child is strikingly demonstrated when we compare the blind with the deaf. Although the former defect receives considerably more sentimental sympathy from the casual observer than does the latter, the blind child has infinitely less difficulties in education. It is true that one of the main entrances of instruction is closed for him, but it is one by which general effects rather than exact thought impressions reach his brain. So long as he has hearing his speech progresses with practically the same rapidity as the normal child, and in consequence his intellectual development proceeds at a nearly equal rate. The congenitally deaf child obtains his general effects through his visual organs, but, by reason of his aural defect, he can neither obtain expressions of exact thought nor formulate his own thought in exact terms. Consequently his school life begins at *seven* in the intellectual condition of a child of *two*. To put it plainly, for five precious years his intellectual development is arrested, and this is, as Kerr Love points out,[5] physically expressed by his relatively smaller head.

But there is yet another very important fact to be taken into serious consideration—the question of *hereditary tendencies to speech*. We represent the at present "last word" of a long line of speaking ancestors—a line so long that the first members thereof who could speak must have existed untold ages back in the world's history. We cannot tell at what precise epoch the first glimmerings of primitive speech made their appearance, but I do not think it would be a very preposterous suggestion to say that *Pithecanthropus erectus*, whose remains bring us to the first dawn of man in Pliocene times, must have possessed the rudiments of speech. The cranial capacity of this fossil is absolutely greater by about 250 c.c. (or over 30 per cent.) than that of the largest skull of the Simiidae, being 855 c.c., the associated brain weight being estimated at 750 gm.[6] The evolution which must have gone on without interruption since the first appearances of primitive man—a period which can hardly be estimated in years—has

slowly elaborated those portions of the central nervous system concerned with speech from the very beginnings of our remote ancestry, and the power of developing similar structural connexions of nerve cells and fibres has been handed down through countless generations and rendered more and more perfect by each, until we have been born with a potentiality for developing as complex and perfect nervous arrangements as those of any individual who has preceded us. It is thus that the centre for speech has been made more apt for expressing exact thought, and this was strikingly evidenced when Helen Keller made the demand "I must speak," a demand which also demonstrated that, not only is there a hereditary tendency to speak, but also a hereditary tendency to develop the general faculties *through* and *by* speech. It was when her centre for speech, with its æons of hereditary tendencies, was allowed to come into play that Helen Keller felt that she was in a new world, and said "My soul, conscious of new strength, came out of bondage, and was reaching through these broken syllables to all knowledge and faith."

In furtherance of this contention, I would like to quote a paragraph from the tenth report of the trustees of the Philadelphia Home founded by the Misses Garrett (p. 3):—

> They [the pupils in the Home] have the same hereditary tendency to talk as hearing children, and even though they may have deaf parents and other deaf ancestors, we know that reaching back to the time of Charlemagne we all had billions of hearing ancestors. *There is no exception to the fact* that every one of them shows a varying degree of desire to use its voice in efforts to articulate from infancy, *as hearing infants do.*—[The italics are mine.—M.Y.]—We believe that every deaf child's imitative powers and its hereditary tendency to talk should be met by the encouragement and aid which is given to the hearing infant's initial efforts. As stated by Sir James Crichton-Browne, "the cerebral centres presiding over the movements of the vocal apparatus—that is to say, the larynx, tongue, lips, &c., are placed in the brain anterior to those which preside over the movements of the hand, arm, and shoulder, and are probably, therefore, in more intimate connexion and communication with what we regard as strictly intellectual centres."

Are we not neglecting an obvious duty as well as opportunities of great value when we take no heed of these hereditary tendencies? We ignore them whilst the deaf-born brain is plastic, suffering them to remain dormant and to perish from inanition. Are they not equally as precious as the "residual speech" we seek to foster in the child who has become deaf after speech has been partially acquired, or as valuable as any residual hearing in the semi-deaf?

It is upon these arguments that I base my contention that the education of the deaf should be made compulsory at a much earlier period than is at present the custom. But any attempt to further this contention is not without opposition, although I believe that this opposition is becoming smaller and less potent every year. At a Council of (British) Head Masters held in 1904, it was resolved to be desirable that deaf children should be placed under proper training at or near the age of five years, and the Norwich Conference of the (British) National Association of Teachers of the Deaf in 1905 further resolved that this earlier education should be made compulsory. A protest from certain teachers elicited an eloquent and convincing rejoinder from Mr. Arthur J. Story, in which his conclusions so thoroughly coincide with my own that I venture to call them to my support for compulsory training at an earlier age. Recently the Council of Head Teachers of Day Schools for the Deaf unanimously resolved "that steps should be taken to lower the compulsory age for attendance at school from seven to five years,"[7] and the mover of the resolution remarked that he would have liked to have inserted that grant be payable on deaf children over three attending school. This shows that the importance of early training is recognised by teachers themselves. My arguments may be summarised as follows:—

1. The child who is normal, save for his deafness, is engaged in a continual struggle to make himself understood and to understand those about him; but unlike the hearing child, his natural yearnings—including his hereditary tendencies to speak—have to go unsatisfied. The deaf child finds some form of expression essential and endeavours to evolve one which can act as a vehicle of thought. Without oral speech, he has to elaborate that gesture language which I have already mentioned as belonging to the pre-speech era and, thus suppressing the play of hereditary speech tendencies, substitutes gesture for speech, a substitution which renders the later acquisition of speech more and more difficult as time goes on. Even if the earlier speech training which I advocate did not completely obviate this expression by gesture (and I believe that it would very largely do so), we should at least give the child the opportunity of becoming bi-lingual, thinking simultaneously in elementary speech and signs.

2. The hearing child develops intellectually without any special care, and he physically outgrows his infancy at about five years of age. Why, when it is in our power to make him early aware of speech as a means of intercourse and for the expression of his ideas, should we prolong this mental babyhood beyond that of the hearing child by denying to him an earlier training? Why should he be forced to remain infantile in mind and be denied the means of mental development?

3. The plastic brain period of the child is past at seven years, and to delay physiological education until that time may be compared to an attempt to model clay that has been allowed to become dry, save that the clay can be wetted anew, whilst the brain-clay of the child is past moistening. Moreover, the muscles which control the speech-organs become to some extent atrophic from disuse if not developed, a circumstance which cannot fail to react disadvantageously upon the speech-centres. "Is it not necessary," asks Bélanger,[8] "to use the larynx as soon as possible? That delicate organ which ought to be the pivot of our method of instruction?" The bad effects of this neglect of the speech-organs under our present methods of oral instruction when the plastic period is past are plainly shown by the artificiality and limited or absent automatism of speech taught when the vocal organs have been for years in comparative idleness.

4. The importance of "residual speech" is universally recognised, and often, if one comments upon the good articulation and intonation of a scholar in a deaf school, one is told "Oh! that case has residual speech." Indeed, one soon becomes able to pick out the children who started with this advantage. These speech remains can be easily and irrevocably lost by neglect. Why should we not recognise the equal value of the hereditary tendencies to speech and to develop the faculties of intelligence through speech, assets which are probably more quickly perishable?

5. It is acknowledged by law and practice that hearing children should begin their pedagogical education at five years. Why should not an equal right be accorded to the deaf? The normal deaf child is not an idiot, an imbecile, or mentally defective; he is no more defective than his normal blind fellow, but, like him, merely suffers from the loss of a valuable sense organ, but, unlike him, it is one the defect of which cuts him off from the most precious of human possessions, the ability freely to exchange thoughts and ideas with his fellows. The hearing child, even when he is blind, is receiving what I have termed "physiological" education at a much earlier age, and I claim that the deaf child has an equal right to this early physiological education, and, as it requires to be carried out by those who are experienced in deaf teaching, it should be provided for by law. The deaf child, of all classes of children, can least afford to lose the full advantage of his most impressionable years, and these years are, physically and physiologically, the most appropriate for the commencement of suitable instruction. I may point out that it is compulsory for the blind child, who has so much advantage over the deaf child, to attend school at five years.

6. It is possible that, by means of this earlier training, the automatic speech attained to by hearing children might be at least partly acquired by the deaf. This automatism, which is really only the outcome of almost ceaseless practice, would be materially assisted by the "synthetic" lip-reading which must be developed in any form of oral teaching. To lip-read with facility requires practice, and the earlier this practice is called into regular use the quicker and more certain it is liable to become. Such facility in lip-reading gives the child command of a means of acquiring new language by sight, a method second only in usefulness to hearing.

Although I am not wholly inclined to the belief that sight can ever be made completely to supplant hearing, I do believe that, by special direction and assistance at a sufficiently early age, the visual centre might be made a very good working substitute for the auditory centre as a stimulus

[7] The Teacher of the Deaf, vol. viii., p. 162.

[8] Loc. cit., p. 52.

for the speech centres. It could, I am sure, be made a centre for the appreciation of language, which would act in relation with that for the production of language.

It scarcely comes within my province to speak of the method by which this earlier physiological training should be carried out, but I am inclined to the opinion that it should be of the nature of kindergarten classes, under experienced teachers of the deaf. These should use elementary articulation lessons calculated to encourage deaf children from the age of three years to chatter at their play, to encourage baby prattle about games, toys, and similar matters of infantile interest. Set lessons during the physiological stage of the deaf child's training should be conspicuous by their entire absence; they should be banished rigidly until the child enters, with some elementary language which he can express orally with a certain ease, upon the pedagogical stage. During this physiological, kindergarten stage of instruction special attention should be paid to language forms which are most easily lip-read and imitated, always remembering that easy articulation should be used most freely. Unless the terms and phrases most easy of articulation and most easily understood by the child are made the dominant feature of the teaching there would be a danger of laying a foundation of bad articulation, a danger which would neutralise part of the good accruing from this proposed early teaching. I would emphasise the paramount necessity of employing only teachers of proved experience, teachers able to judge the necessities of the child, able to enter into his mental processes—in other words, to see with his eyes—and able thoroughly to *interest* him and to make him realise the value of spoken language as a method of communication. The words and phrases which could be grasped synthetically and reproduced with a fair amount of accuracy would come first, the difficult "elements" taught by articulation lessons being gradually led up to and introduced.

If there is any possibility of the visual centre being trained to take up the duties of the auditory centre as a stimulus to those presiding over speech, this early physiological course would take full advantage of it, and would train the child into a *habit* of using his eyes in place of his ears. The possible danger of laying a foundation of bad articulation could be obviated by the experienced teacher, and the chief aim should be to obtain a facility and fluency of speech which would prevent that artificiality so often complained of as characteristic of speech in the deaf.

It must be remembered that this early training of the deaf was approved of in the United States, by the House of Representatives in Pennsylvania, as long ago as 1891. In the discussion upon the Bill then passed, a member of the House made the astonishing statement that it would injure little deaf children mentally and physically to be taught to speak before they were of school age. It would be equally logical to say that such teaching similarly injures the normal-hearing child. The extraordinary folly of this remarkable assertion is amply demonstrated by a perusal of the reports of the Garrett Home and of the opinions of those who have visited it. Something has already been done in the cause of early training in London, and I would point out the encouragement afforded by the following paragraph in the annual report for 1909 of the school in Fitzroy-square:—

> A preparatory or kindergarten class has been opened in the schoo for young children, and the character of the work which has been accomplished fully justifies the innovation and strengthens the belief that it serves a distinctly valuable purpose.

In one of our London County Council Deaf Centres is a child, now aged 5 years. She was admitted at the age of 3½ years, and is a congenital total deaf-mute. During her first term she did not appear to be learning much speech or figures, but she showed great imitation. She wrote with chalk on the blackboard and on brown-paper forms of parts of letters, &c., and imitated the motions of the mouth. She threaded beads, sewed embroidery cards, played games, and imitated the actions of older children. In her second term she learned some sounds and spoke them, and was keenly interested in kindergarten occupations. During her third term she acquired a vocabulary of six words, could speak long vowels and nearly all the consonants. When in her fourth term she attained the age of five years and can lip-read well. She knows all sounds and combinations of Stage I., written and oral, and has a vocabulary of 38 words and 18 actions. In language she can answer orally such questions as "What have you?" "What colour is the ——?" and knows the colours blue, black, yellow, and white, naming them correctly. She can knit, sew on canvas, and do the usual kindergarten occupations. She talks a great deal[9] and lip-reads well in class. Her synthetic lip-reading for orders is good. She is bright and happy in school, is seldom absent, and is trying for a medal. She has half an hour's walk to the train by which she travels to and fro, and her parents affirm that they have never regretted sending her to school at such an early age. This child of 5 is, therefore, at the stage which, under the present system, is only attained by children who have entered at 7 when they are past, or well on towards, 9. If so much can be done for a normal totally deaf child in the ordinary classes of a deaf school, what could not be achieved in a special class such as I have suggested? Another case, a boy, a congenital deaf-mute, concerning whom his parents consulted me in May, 1907, when he was 3½ years old, was admitted at my special request by the late Mr. William van Praagh to Fitzroy-square. His success has been quite equal to that just related, to the great satisfaction of his parents.

I have mentioned these two cases as practical illustrations in favour of early education and to avoid the adverse criticism that may be raised by a certain section of educationists as to the advisability of placing a deaf child at a special school at so young an age. I would point out, if I am accused of a desire to drag children of tender years from the care of their parents, that the physiological education of the deaf pre-eminently necessitates a special teacher, and that no parent, however willing and well-intentioned, can carry it out unless he is himself an experienced teacher of the deaf. I believe that the object which I advocate could be attained by short school hours with plenty of play—play being, indeed, itself a means of teaching—upon, say, five half-days a week, the child being absent from home only during those times. Parents would soon become impressed with the advantages that their children were receiving, and could help the teachers by home influences. Indeed, not only have the parents of the two children just cited expressed their lively appreciation of, and satisfaction at, the results obtained, but other mothers and fathers have stated to me that they were wishful for such an arrangement for early training.

I believe that, under such circumstances, whilst brain and larynx are more plastic than at seven, or even five, the speech centres could be stimulated to better development, and that the hereditary tendency to speak could be preserved, encouraged, and fully utilised, so that some degree of automatic speech could be made possible. Surely such a course would greatly increase oral successes both in number and degree, give fewer oral failures, lead to further improvements in classification, emphasise individuality, make the deaf child more nearly approach to the normal child at seven years, and enable us to distinguish earlier the mentally deficient and the mentally deficient deaf. I need scarcely say that this applies equally to those cases of acquired deafness who, having lost their hearing at two years and onwards become, under existing conditions, mute before seven years.

I have now dealt briefly with all the present needs, which would go to make a better system of educational treatment for the deaf, postulated in my first article, save one. This was the need of endeavour to diminish the number of deaf children requiring special education by the application of eugenic principles to deaf-mutism in the case of the congenitally deaf, and by a better care of the ears in children by medical practitioners. The latter has already been discussed to an extent sufficient for the present needs of these articles. The former I have gone into at some length in a paper read before the Eugenics Education Society last year.[10] This paper was based upon facts gathered from the examination of 691 deaf children of both sexes in the London County Council's schools, of whom 407 had acquired their deafness after birth, or whose condition was doubtful in origin, and 284 were undoubted congenital cases.

The difficulties which stand in the way of obtaining accurate information and adequate family histories in cases of congenital deafness are very great, especially among the class from which these children are drawn. Very few

[9] She early began to try to talk, evidence of her hereditary tendency to do so, a tendency which, I venture to believe, has been awakened and developed by her early training in oralism.

[10] Eugenics and Deaf-mutism, Eugenics Review, January, 1911.

parents know their family histories, medically speaking, beyond those of their own immediate progenitors, and their knowledge of the collateral branches of their families—a matter of the highest importance—is even less. The difficulties are, if anything, greater in dealing with families having the taint of insanity or alcohol, although the sojourn of some member in a lunatic asylum is sometimes regarded as a sort of family distinction, a matter, maybe, for congratulation. A similar feeling is sometimes met with in regard to deaf-mutism, as is exemplified by a proud father, who greeted me with the words "We've four generations of born-deafers, and all on the missus's side!"

It is impossible to enter into any detail here of the results of this small investigation into the histories of the 691 children dealt with, but I will give some of the figures obtained, referring the reader to the original paper for further information. Out of the 284 congenital deaf-mutes, in 43 cases, or 15·4 per cent. of the whole, no family histories of any kind were obtainable, and in 132 cases, or 42·9 per cent. of the whole, there was no history of deafness or of any fact of importance which might bear upon the cause of the defect. In 13 families, or 4·5 per cent. of the whole, whilst there were no ascertainable data regarding the presence of other deaf-mutes, there were histories of neurosis or of alcohol. In one of these cases, both paternal grandparents died from "paralysis," the father was mentally defective, one paternal uncle suffered from "fits," and one paternal aunt died from phthisis; the case himself was congenitally deaf and mentally defective and he had a mentally defective brother. Another family, of which the mother was alcoholic, comprised one boy congenitally deaf, one boy an idiot, one boy with hydrocephalus, and a pair of twins, one of whom died from "fits," the other from neglect. In 89 families, or 31·6 per cent. of the whole, there was a family history of deafness, acquired only in ten of these. The elimination of these ten cases left 79 families (24·5 per cent.) with histories of congenital deafness, distinct from those in which there was consanguinity. I have no doubt that there would be found many more families with a history of congenital deaf-mutism among the 284 children born deaf, were it possible to get at the truth with more precision. Consanguinity was noted in 14 families, or 4·9 per cent., and of these the parents were first cousins in nine cases, second cousins in one case, whilst in four cases the degree of cousinship was not ascertained. As a contrast to these cases, consanguinity was present in only three cases (0·7 per cent.) out of the 407 children whose deafness was definitely known to be acquired after birth or to be doubtful in origin. The number of congenitally deaf in each family was ascertained to be: one in 40, two in 18, three in 16, four in 4, and five in 1 family.

According to the table published by Holger Mygind,[11] drawn from statistics of 7063 deaf-mutes from Nassau, Cologne, Magdeburg, Denmark, Saxony, Ireland, and Mecklenburg, about 15 per cent. of the marriages which result in deaf-mute offspring produce two or more deaf-mute children. Probably the percentage, could very accurate statistics be obtained, would be found to be greater, for it is only right to mention that in Mygind's table many of his statistics include deaf-mutes in general and not congenital cases in particular. Only his Irish statistics refer solely to congenital cases, and in these out of 3045 marriages 2506 produced one case each, 324 produced two, 149 three, 38 four, 22 five, 5 six, and 1 the enormous number of ten deaf-born children. The percentage of marriages in Ireland (taken in 1881) resulting in more than one deaf-mute was, therefore, 20·9.

It will be of advantage to sketch very briefly the present state of our knowledge as to the influence of the two factors, heredity and consanguinity, which occur with sufficient frequency in the histories of those born deaf to warrant their being regarded as effective causes of congenital deafness. The opinions expressed as to the value of these two factors have differed widely from that of Kramer, who made the somewhat dogmatic statement that "deaf-mutism is not a hereditary disease,"[12] to that of Wilde, who was the first to lay stress upon the opposite view. To reach the truth of the matter, one must look at the idea of heredity from a wider standpoint than that of mere direct transmission and consider not the direct ancestry, but the collateral family tree. The matter is expressed so well by Kerr Love in his work on "Deaf-Mutism" (p. 101) that I may be excused for making a somewhat lengthy quotation from him.

> It is not enough to seek for the cause of congenital deafness only in the parents of the affected child. These may hear or be deaf, but that single fact teaches little. Indeed, in the first generation the tendencies of two congenitally deaf parents may so counteract each other that the result is a hearing child; but reversion will ultimately assert itself. The second generation will probably follow the grandfather or grandmother with greater faithfulness, and a deaf grandson will result, or the characters of a prepotent progenitor separated by many generations may crop up, and an unlooked-for outbreak of deafness may take place. In calculating, therefore, the chances of deafness in a family in which it is feared, our view must not only include the immediate progenitors, but the whole family antecedents on both father's and mother's side. This statement is of practical importance; it takes all, or nearly all, the value out of the proposal to prohibit the intermarriage of the congenitally deaf, for, as has been shown, the hearing members of a deaf-mute connexion send down the tendency to deafness with as great certainty as the deaf members.

Congenital deafness is less frequent in the direct ascending line (grandparents and parents); more frequent in the collateral branches (great-uncles and great-aunts, uncles and aunts, grandparents' cousins, parents' cousins, cousins and second cousins); and most frequent among the brothers and sisters of the deaf-mute. Mygind points out[13] that, out of 553 deaf-mutes, of which 226 were congenital, in Denmark, 110, or about one-fifth, had one or more congenitally deaf brothers and sisters, but only 37, or about one-fifteenth, had one or more deaf-and-dumb relations in more remote degrees. That is to say, there was one deaf-mute relative, not including parents, brothers, and sisters, to every sixteenth deaf-mute. Those who hold the opinion that congenital deafness is not hereditary cannot say that the defect is as common amongst the relatives of normal people.

The factors which may influence the heredity of deaf-mutism are just as variable as in the case of other abnormalities. The special character of the parent may be present in only a few of the offspring, or an entire generation may be unaffected. I am not aware that Mendelian principles have as yet been applied to congenital deafness, and the difficulty of obtaining sufficient data for practical use in this regard is very great.

Consanguinity of parents, like heredity, has given rise to much dispute. Some consider that such marriages are harmless, taking as their point the beneficial results of in-breeding in domestic animals. Without entering into details it may be pointed out that the conditions are not similar, for with the artificial selective breeding of animals only perfect specimens are admissible, whereas it is notorious that no such precautions are taken in the consanguineous marriages of man. Mitchell[14] found that in 400 deaf-mutes 1 in every 16 had parents who were blood relations,[15] whereas the proportion of cousin marriages in Great Britain is probably about 1 in 60 or 70. In Denmark, according to Mygind,[16] the proportion of cousin marriages is about 3 to 4 per cent. of all marriages, but 6·75 per cent. of the deaf-mutes admitted to the Royal Deaf and Dumb Institution in Copenhagen were the result of such marriages. A fact which bears upon this question is the proportion of deaf-mutes amongst different religious sects having different marriage customs. Congenital deafness is much more common amongst Jews than amongst Protestants and Roman Catholics, and it is more common amongst Protestants than amongst Roman Catholics. Now Jews intermarry largely, whilst Roman Catholics discourage cousin marriages, and Protestants permit such unions.

A monumental piece of work upon the question of the causes underlying congenital deaf-mutism is that by Fay,[17] which contains exhaustive statistics of 4471 such marriages. These statistics show that marriages of the deaf are somewhat but not very much less productive than ordinary marriages, and that the marriage of deaf persons (taken as a whole without regard to the character of their deafness) in which one or both partners are deaf are far more liable to result in deaf offspring than marriages in which both partners are hearing. A chapter of this work is devoted to consanguineous marriages of the deaf, of which there were 31 in the 4471 marriages dealt with (0·693 per cent.). An examination of these showed that the percentage of deaf children

[11] Mygind: Deaf-Mutism, London, 1894, p. 53.

[12] It is an obvious error to speak of congenital deafness as a "disease," it is more correct to describe it as a "defect."

[15] My own figures, given above, show 1 in every 22½.

[16] Mygind, loc. cit., p. 87.

[17] Marriages of the Deaf in America. Washington: The Volta Bureau, 1898.

born from marriages reported as consanguineous was nearly four times as great as from marriages not so reported. In the concluding advice given to the deaf, therefore, it is stated that under no circumstances whatever should union be permitted among those who are related in any degree of consanguinity. It was a study of United States statistics that led Graham Bell, the inventor of the telephone, to write his warning pamphlet, "On the Formation of a Deaf Variety of the Human Species in America."

Interesting examples of communities are extant which give support to opposite views as to consanguinity. Of these it will be sufficient to quote two. In the island of St. Kilda, off the Outer Hebrides, intermarriage has gone on for centuries, yet no case of congenital deafness has ever been known there. On the other hand, at the Island of Martha's Vineyard, on the southern coast of Massachusetts, where intermarriage also obtains, there were, in 1880, 20 congenital deaf-mutes in a population of 500.

A possible explanation of conflicting facts met with in discussing the effects of consanguinity has been suggested by Mackay,[18] based upon the investigations of Thomson into the marriage customs of Fiji. In Fiji, cousin marriages are considered from two aspects: (1) where the contracting parties are the children of two brothers or of two sisters; and (2) where the contracting parties are the children of a brother and a sister respectively. Thomson has shown that the relationship between the children of two brothers or of two sisters is exactly the same as the relationship between the children of the same parents, and therefore marriage between two such children is strictly forbidden. On the other hand, cousins of opposite sexes, of whom the father of one is brother to the mother of the other, are said to be "concubitants,"[19] that is to say, marriage between them is not only encouraged, it is obligatory. From an examination of census figures, taken with a view to the study of Fijian marriages, Thomson found that, as to both fecundity and vitality of offspring, the marriages between concubitants are superior to those between relations (not concubitants), or between fellow townspeople (not related), or between natives of different towns. In contrast with this, it appeared that marriages between relations (not concubitants) are greatly inferior to those of any other class. Whilst pointing out that this consideration, applied to the investigation of deaf-mutism, would mean the preparation of entirely new statistics, Mackay believes that, if this were done, it might reconcile present discordant opinions.

It is impossible totally to eradicate congenital deafness for a certain number will always appear, like other sporadic cases of defect. Their number could, however, be enormously reduced by the application of eugenic principles. If deaf-mute marriages, the union of blood relations, and the union of alcoholics, syphilitics, and those with a family taint of insanity could be prohibited, that alone would be of great assistance. We can at present, however, only educate public opinion. The medical practitioner has many grave responsibilities upon his shoulders, and not the least important of them is his duty to the State. He has it in his power to educate the public both by precept and by example, and he should never neglect an opportunity of using that power. It is a great pity that the doctor is not more often heard in Parliament, not as a crank, but as one who has exceptional opportunities, by education and experience, of giving valuable and practical aid to the State. But, for many reasons, the medical profession has, in this country at least, to work silently. Honours fall more readily to the destroyer than to the saviour, to the talker than to the thinker, and it needs repeated hammering to make people understand that it is the saviour and the thinker who are really of most worth. It is the medical practitioner who should be foremost in eugenics, and from what I have said it is evident that in the application of eugenic principles it would be possible greatly to reduce the number of deaf-born persons requiring special education. Out of 691 deaf children we have seen that 284, or over 41 per cent., were congenital. Could these be eliminated greater attention could be paid to the 407 acquired cases, their classification would be simplified, and the results of education would be better.

Queen Anne-street, W.

# NOTES ON THE DURATION OF INFECTIVITY OF ENTERIC FEVER

## AS ILLUSTRATED BY REPEATED BACTERIOLOGICAL EXAMINATION OF 27 CASES.

BY ALFRED HARRIS, M.B., CH.B. VICT., D.P.H. CAMB.,
ASSISTANT MEDICAL OFFICER OF HEALTH, SOUTHAMPTON.

ATTENTION has been given recently to the fact that patients convalescent from enteric fever pass, for a variable time, typhoid bacilli with their stools and urine. In order to estimate the length of time during which the bacilli may continue to be excreted a routine examination of the stools has been carried out during the last few months of all enteric fever patients treated in the Isolation Hospital, Southampton.

The usual routine methods have been employed. A small portion of the stool is mixed with sterile water, and two Petri's dishes are inoculated by means of a glass rod. Both dishes are inoculated by the same rod, the reason being that the first plate will as a rule contain, on being incubated, too many colonies; the second plate generally shows the colonies quite separate, and subcultures can be easily carried out. If the colonies on the plate are too numerous, most of the lactose of the medium is used up, and consequently there will be some B. coli colonies which do not show the characteristic change. For this reason an overcrowded plate should be discarded when subculturing colonies.

The following media have been employed in this investigation in order to make the first differentiation between the B. coli and the typhoid colonies: (1) McConkey's bile-salt neutral-red agar; (2) Endo's fuchsin agar; (3) Werbitzki's China-green agar; (4) Conradi-Drigalski's medium; and (5) Faucus's brilliant green agar. The principle of most of these media is the same. Lactose is added to the medium, which is decomposed, with formation of an acid, by the B. coli and not by the typhoid bacilli. The acid so formed acts on the indicator in the medium and changes its colour, thus enabling the B. coli group of organisms to be separated from the typhoid group.

There are other organisms, however, occurring in the intestines which are non-lactose fermenters, and therefore subcultures are necessary in order to identify the typhoid bacillus. The following additional tests are made: 1. Litmus milk cultures should show acidity and no curdling of the milk. 2. Indol ought not to be produced on growing the organism in peptone solution. Some varieties of peptone do not show indol production with any organism, so that the peptone solution should be tested beforehand with a known indol-forming organism. 3. Hanging-drop preparations should show a motile bacillus. 4. The organism should produce acid but no gas in glucose and mannite litmus peptone solutions.

As regards the choice of a medium for the preliminary separation of the organism, I have found McConkey's neutral-red bile-salt agar to be the most reliable. Endo's fuchsin agar is very sensitive, but it possesses two disadvantages: 1. It changes its colour and becomes useless if exposed for any length of time to the light. 2. The plates must be examined frequently at short intervals; if left too long in the incubator the deep-red B. coli colonies tend to spread and obscure the colourless non-lactose-fermenting colonies.

Faucus's brilliant green agar does not possess any advantages over McConkey's medium and is a little more difficult to prepare. Werbitzki's China-green agar differs from all the other media in not containing lactose. It consists simply of a 3 per cent. nutrient agar medium brought to a reaction of + 13 (Eyre) and containing 0·003 gramme of Grübler's China-green in every 100 c.c. of the medium. On this medium, as Professor McWeeney points out, about 75 per cent. of the B. coli colonies are suppressed, and the developing colonies are small, opaque, and point-like. The typhoid colonies are larger and darker in the centre. Professor McWeeney recommends this medium for the detection of typhoid bacilli in stools.

The stools of 27 patients have been examined and cultures made during the convalescent stage after the temperature had reached normal. In cases showing a positive result weekly examinations were made until a negative result was obtained. Of course, in a hospital it is not practicable to

| Number of case. | Sex and age. | Date of admission. | Day of disease on admission. | Date of normal temperature. | Duration of pyrexia after admission in days. | Dates of examination of stools. | Number of days of normal temperature preceding examination of stools. | Result. | Remarks. |

* An irregular pyrexia, due to the abscesses, commenced on Oct. 7th, the temperature again becoming normal on Nov. 2nd.

keep patients until assurance is made that they will not become carrier cases; several examinations showing negative results are necessary to make certain that the patient will not become a carrier, as it is well known that carriers often pass the bacilli intermittently.

Some importance may eventually be ascribed to discovering the period when a patient ceases to pass the bacilli, as probably it will be found that these cases are free from the liability to have relapses. I cannot, however, give any proofs of this at present. A glance at the table will show the variability in the period when a negative result was obtained.

The persistence of infection bears no relation to clinical signs; the patient in No. 9, who showed typhoid bacilli in the stools 78 days after the temperature was normal, was a mild case with little diarrhœa.

A consideration of the table tends to show that carrier cases do not have such a marked influence on the spread of the disease as might be thought possible, because "return" cases of enteric fever are very rare, and as most hospitals discharge their patients without a bacteriological examination of the stools a fair proportion must be sent home with typhoid bacilli still present in the intestines.

I am indebted to the medical officer of health, Dr. Lauder, for permission to publish this article.

Southampton.

Dr. George M. Robertson, lecturer on mental diseases in the University of Edinburgh, and physician-superintendent of the Royal Morningside Asylum, Edinburgh, and Dr. A. R. Urquhart, physician superintendent of James Murray's Royal Asylum, Perth, have been elected corresponding members of the Society of Psychiatry of Paris.

THE WEST HAM AND EAST LONDON HOSPITAL.—At a large public meeting of the governors and subscribers of this charity, held in the council chamber of the Town Hall, Stratford, by kind permission of the mayor and corporation, the alteration of the name of the institution to "The West Ham and Eastern General Hospital" was unanimously confirmed. The hospital is now in every sense of the term a general hospital, having surgical and medical wards for both male and female cases, as well as ample accommodation for dealing with accidents.

## SPOROTRICHOSIS.

BY E. VON OFENHEIM, M.D. LEIPZIG, M.R.C.S. ENG., L.R.C.P. LOND.

THE disease known as "sporotrichosis" seems to be sufficiently rare to justify the publication of notes upon a case which just recently came into my hands. Further history of the case and the effects of the therapy may allow a more complete picture of it to be given.

The patient, a female, aged 18¾ years, had been quite a healthy child up to six years ago. The family history does not show anything of importance; neither tubercle nor specific disease can be traced. Six years ago the patient had a glandular swelling on the left side of the neck, which was operated upon, the glands being removed. She was quite well after that until about three years ago, when the whole of her neck—that is, probably all the cervical glands—began to swell, the condition being diagnosed as Hodgkin's disease. After a few months a diagnosis of tubercular glands was made by another medical man, and the patient was submitted to X ray treatment, which apparently at one time caused the glands slightly to decrease in size, but they rapidly increased again, and the prolonged X ray treatment did not seem to have any further effect.

The case came into my hands on Nov. 18th, 1910, and from the opsonic index to tubercle (which varied between 1·22 to 0·73) I concluded that the diagnosis of tubercle must have been the correct one, and the patient was submitted to a course of inoculations with B.E. tuberculin. At the same time there was a fairly hard, not very tender, swelling over the middle third of the left tibia which was sometimes painful, especially at night. This swelling had existed (as I was informed) since September, 1910.

The three possibilities which were taken into consideration at the time were: (1) tubercular periostitis or osteitis; (2) gumma; and (3) osteo-sarcoma. No. 1 seemed to be the most probable one in consideration of the condition of the glands of the patient. To exclude No. 2 a Wassermann test was made which proved negative. To decide No. 3 the effects of the tuberculin treatment could be watched. There existed also a sinus behind the left ear, above the mastoid process, the result of an incision designed to lead

to a broken-down gland, but from which no other discharge but blood was obtained.

By Feb. 4th the glandular swellings in the neck had considerably decreased, the circumference of the neck being diminished by 1½ inches; at the same time the swelling on the tibia was more marked and was apparently fluctuating. On that day, with an aspirating needle, about 2 c.c. of blood were withdrawn from that swelling, and were planted out on agar, serum agar, and broth. The microscopical examination showed only blood and no organisms could be discovered by direct examination. The leg felt very comfortable for the next few days, but became very painful again, and by Feb. 15th the swelling had markedly increased and was distinctly fluctuating and very tender. It was again aspirated, but only some very thick, dark-brown, tarry fluid was obtained with great difficulty, which proved on examination to be altered and partly congealed blood. This appearance, taken together with the fact that in spite of the glands going down under the tuberculin treatment, the swelling of the tibia had increased, made me suspicious of malignant disease.

Cultures were made again from the fluid withdrawn, and on the next day the patient was removed to St. John's Hospital, Lewisham, S.E., where the swelling was opened by a longitudinal incision of about 4 inches. Congealed blood only was found on the tibia. The bone itself was stripped of the periosteum to an extent of about 2 inches, and two small sinuses were noticed leading into the bone. The bone was opened, and it was found that these two sinuses led into a cavity of about ½ inch in diameter and 1½ inches long. This cavity contained some semi-gelatinous substance, but was not in any communication with the medullary cavity. It was afterwards plugged with iodoform. The wound was stitched up and only drained at the lower angle. Since then the wound has united by first intention, and there was never any pus or discharge of any kind. The temperature, which showed before the operation variations between 97·6° and 100·5° F., went up after the operation for several nights to 103° and even 104°, the patient feeling quite well in spite of it.

The cultures which were taken at the time of the first aspiration (Feb. 4th) have grown within seven days a few small colonies which microscopically looked like yeast, and I supposed that I had in those cultures an accidental yeast contamination, as yeast infections are very rare, although there are several of them on record in the literature.

The cultures which were taken at the time of the second aspiration have grown in six days the same organism—that is, a great number of a Gram-positive, round or oval-shaped organism almost of the size of a red blood corpuscle, some of which showed some differentiation of the protoplasma. Subcultures, which were made on various sugary media, showed that the organism, unlike any yeast, did not produce alcohol, nor acids, nor any kind of gas. Milk which was planted out with it did not coagulate, nor was it altered in its reaction in any way in ten days, and the organism did not seem to grow well in it. Subcultures, which were planted out on glucose agar, grew much more readily, and after two or three generations they are growing now within 24 to 48 hours. At room temperature (20° C.) they seem to grow better than in an incubator at blood temperature. From these subcultures smears were stained in various ways, in some of which a mycelium was discovered and to which the above described round-shaped spores were hanging in clusters. Cultures which were planted out with a platinum wire, which was inserted into the sinus behind the ear of the patient, have grown exactly the same organism in pure culture.

Although it would be rash to make an absolutely definite statement, I feel convinced that this is a case of sporotrichosis, as described by Beurmann, Ramond, Brodier, Gastou, and others; and so far the bacteriological appearance is in accordance with the descriptions given by Duval and Monier-Vinard. The one point in which this case differs somewhat from those which have come to my knowledge up to now is the localisation of the disease in the bone, but there are some typical cutaneous lesions in this patient as well, of the existence of which I was only informed after the operation, as the patient did not attach any importance to them herself. These cutaneous lesions are on the external surface of the right thigh—not the same leg on which the bone lesion was—and consisted of three little ulcers, two of which are skinned over and only show a purple discolouration, whilst the lowest one is still open, showing a tendency to granulate, but does not discharge. Cultures from these lesions have been taken and have grown the same organism as from the other lesions in pure cultures.

A good many cases of sporotrichosis have been diagnosed and published in France, in America, and a few also in Germany; but as far as I have been able to look through the literature in this short time I believe that the above is the first case of this kind to be recorded in England.

Weymouth-street, W.

## TREATMENT OF RODENT ULCER BY CALCIO-PHOSPHATE OF URANIUM.

BY ALBERT CHURCHWARD, M.D. BRUX., M.R.C.P. EDIN., M.R.C.S. ENG.

IN the treatment of rodent ulcer there has been during the last few years a great advance in our knowledge of the subject, and consequently much benefit to our patients. There yet remains, however, a wide scope for new methods, and I am anxious to put before my colleagues in the profession a new treatment which in my hands has, so far, proved an unqualified success. Up to the present time I have only treated three cases of this disease with this remedy, and therefore feel much diffidence in bringing the treatment before the notice of the profession generally, my excuse, if any is necessary, being that two cases are completely cured and the third is getting rapidly well.

The mode of application and treatment generally is simple and inexpensive, in which respect it differs from radium bromide. Whilst experimenting with calcio-phosphate of uranium I found this mineral to possess great radio-activity. This name was given to me by Dr. George Prior, Keeper of Minerals at the British Museum Natural History Museum, South Kensington, after having examined my specimen of mineral and comparing it with others in the museum. As I had no means to measure the radio-activity of the mineral I had some radiographs taken, two of which I here submit. Fig. 1 shows the amount of "light" emanations given off during an exposure of three hours. Fig. 2 is the shadowgraph of a coin taken through half an inch of wood with six hours' exposure. The radiograph and shadowgraph here depicted were procured: (1) by putting an ordinary photographic sensitised plate in a dark room and leaving the mineral upon it for three hours; and (2) placing a piece of wood half an inch thick over the coin which rested on the plate and the mineral lying on the wood—exposure six hours.

The following are the cases treated:—

CASE 1.—A man, aged 47 years, had a small rodent ulcer on the right side of the nose, had noticed it for some months and treated it with boric acid and ung. zinc. oxidi himself, but as no improvement took place he came to me in September last. An exposure of three hours a day cured this in five weeks.

CASE 2.—A woman, aged 50 years, had been treated for rodent ulcer for some months with X rays. She stated that she was no better but rather worse than when treatment was commenced. She also came to me last September. An exposure of four hours a days cured this in nine weeks.

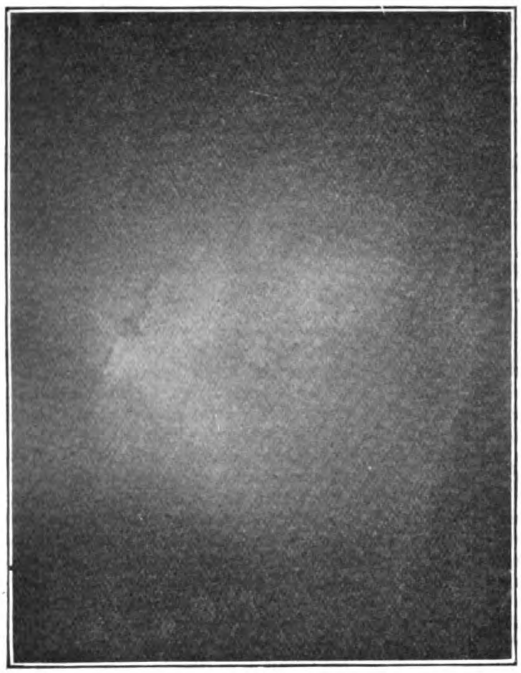
CASE 4.—The patient, a woman, aged 49 years, is partially paralysed. She is suffering from tumour in the brain, and developed rodent ulcer on the left side of the nose, which was treated with X rays for four months. She did not improve, but became rapidly worse. I began treating it four months ago, with exposure of two hours a day for the first month, three hours the second month, and then four hours a day. It is now almost well, and about one-tenth of the original size (see Fig. 3). The healed tissue shows how large this ulcer was before I began treating it.

I much regret that Cases 1 and 2 refused to be photographed, but the photograph of No. 3, which was taken in my presence by Mr. Norton Collins of South Norwood, shows the present condition of the patient.

I am also using this treatment in two cases of inoperable cancer, but have not yet had sufficient time to say if any permanent benefit will result.

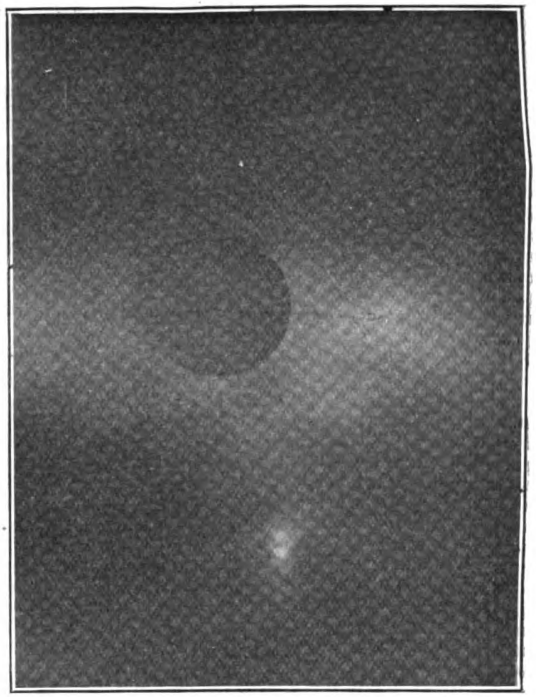
Before entering upon treating any case with the mineral it is absolutely necessary to prove how much radio-activity

FIG. 1.



Showing amount of "light" emanations in three hours.

FIG. 2.



SLowing shadow of coin through ½ inch of wood (6 hours' exposure).

it possesses, as some specimens possess very little, whilst others contain a large amount. From experiments I have made I should say that the mineral should contain as much radio-activity as that shown in the radiograph (Fig. 1) in order to be effective. This I regard as the *lowest* standard of efficiency.

The mode of treatment is simple. After proving that your calcio-phosphate of uranium is sufficiently radio-active, as per above, place a piece of lint over the ulcer and let the mineral rest on this for three hours each day, which after a week can be increased to four or five hours. If any dermatitis is produced in the surrounding tissues leave the treatment off for two days, and then apply for an hour, or two hours only, for the first week, after which increase the time gradually. Dermatitis in the surrounding tissues was set up once only in my cases after an exposure of five hours.

It is wise to wrap a piece of lint or bandage round the mineral and to keep this on permanently because the yellowish-green crystals of the calcio-phosphate of uranium are easily broken and detached from the matrix on which they are deposited, and would therefore depreciate the radio-active power of the mineral.

FIG. 3.

The two "black spots" here portrayed show portions of the ulcer not quite well; the lighter portion shows where the ulcer has healed. The healed part is much larger than depicted above, but it has healed so well that there is so little difference in the surrounding tissues that photography does not show it.

The value of this treatment is this: 1. It is not expensive, as is the case with radium bromide, and therefore within the means of any general practitioner. 2. The mode of treatment is so simple that patients can be treated in their own homes, the case being left in charge of a nurse after the general practitioner has seen that the mineral is properly applied and in the position required.

In placing this treatment before my brother medical practitioners, more especially those who are unable to procure radium-bromide or "snow," I feel sure that they will find it quite as satisfactory as the other treatments, although I admit that a little more patience is required. It is less expensive, and last, but not least, the "scar" left is certainly less than in any other treatment I have seen.

Anyone interested in this treatment can see the subject in Case 3 by communicating with me, and it is certainly a severe test of the efficiency of the treatment owing to the low standard of general health of the patient, on account of her other ailments.

South Norwood, S.E.

## AN UNUSUAL CASE OF INTESTINAL OBSTRUCTION.

BY E. A. WRIGHT, M.B., B.C. CANTAB., D.P.H.

THE patient, an unmarried girl aged 21 years, was admitted to the Romford Cottage Hospital on Oct. 13th, 1910. She complained of abdominal pain and vomiting, and stated that the bowels had not acted for several days, in spite of repeated injections. On examination the patient presented a pale, sallow appearance; tongue moist and clean; pulse 116, temperature 97·5° F., and respirations 24 to the minute. The heart and lungs were normal. Abdominal examination revealed the presence of a hard rounded lump in the right epigastric region of about the size of an orange. This was tender to deep pressure, and did not move with respiration. Per rectum a hard, small, non-tender moveable mass could be felt. The patient gave a history of a similar attack a year ago which was relieved by enemata. She also stated that she had suffered from constipation with frequent attacks of vomiting for some years, and had been under treatment at a London hospital for indigestion. A diagnosis of fæcal impaction was made; hot poultices to the abdomen, oil and soap enemata, and subcutaneous injections of atropine sulphate were tried. During the first 24 hours of this treatment the patient's condition improved; the vomiting ceased and the pulse-rate dropped to 108, the temperature remaining normal. No action of the bowels was obtained. On Oct. 16th the vomiting started again and the pulse-rate rose to 120. Eserine sulphate (1-20th grain) was given subcutaneously, and the faradic current was applied to the abdomen. No relief was obtained from this treatment, and on the 17th the patient's condition became much worse, and laparotomy was decided on.

The abdomen was opened by a 4-inch incision 1 inch to the right of the middle line. A coil of distended small intestine and a portion of omentum at once protruded through the wound. The lump previously felt was explored with the hand and found to be hard, smooth, and rounded, and to extend a considerable distance upwards and to the left. The abdominal incision was enlarged and the cause of the obstruction in the intestine was sought for. A firm lump about 3 inches long was found completely blocking the lumen of the small intestine; beyond this point the intestine, large and small, was quite empty. The peritoneal cavity was shut off by packing, and the bowel was opened by a small incision. The obstructing mass was found to be hair tightly matted together. This was removed, and the wound in the intestine was closed by Lembert's sutures. The other lump was then examined and found to be in the stomach, which organ it completely filled. The stomach was opened by an incision about 3½ inches long in the anterior wall, and the mass was removed with some difficulty. This also was found to consist of an enormous mass of tightly matted hair, which was found subsequently to be of the following weight and size: weight, 2 lb. 12¾ oz.; length, 11¼ inches; and circumference, 10½ inches. The wound in the stomach was treated in a similar manner to that of the intestine. The peritoneum was irrigated with warm saline solution, and a quantity was left in. The peritoneum and muscular layer were taken up in one layer of sutures, owing to the gravity of the patient's condition, and the abdomen was closed.

The patient rallied well from the operation, and her condition on the following day was much improved. The bowels were acting copiously and there was no vomiting. The pulse-rate continued high. Owing to severe diarrhœa, with frequent and very offensive stools, it was impossible to feed per rectum, and the patient becoming dangerously exhausted feeding by the mouth was started on the third day after the operation. This was followed by a temporary improvement, but the diarrhœa returned with increasing severity and continued in spite of treatment till Oct. 23rd, six days after the operation, when the patient died.

The above case seems to me an interesting one for several reasons. 1. Although hair masses in the stomach have been fairly frequently described, they are rare as a cause of intestinal obstruction. 2. The enormous size of the mass in the stomach with the comparatively slight symptoms it had caused. 3. The mental condition of the patient. A large proportion of cases of this condition described have been lunatics. This patient was a bright, intelligent girl, with no history of hysterical attacks. Her relatives tell me, however, that for many years she had been in the habit of pulling and biting at her hair when reading or when her attention was otherwise engrossed, showing that the habit had become almost an unconscious one.

Romford.

## INFANTILE SCURVY IN A CHILD FED ON STERILISED MILK.

BY FRANCIS BRACHI, M.R.C.S. ENG., L.R.C.P. LOND.,
ASSISTANT SCHOOL MEDICAL OFFICER TO THE BOROUGH OF PORTSMOUTH; LATE HOUSE PHYSICIAN, VICTORIA HOSPITAL, CHELSEA.

*With Remarks by* J. WALTER CARR, M.D. LOND., F.R.C.P. LOND.

ON May 12th, 1910, a female infant, aged 7 months, was admitted to the Victoria Hospital for Children, Chelsea, under the care of Dr. Carr. A few days previously her mother had noticed that the child's legs were swollen and painful. This commenced in the right knee, the left being affected two days later. The swellings were very tender and painful, and the child cried whenever the limbs were touched or moved. She was very restless at night and perspired freely about the head. There was no vomiting. The bowels were regular, the motions being of normal colour. There was no reason to suspect any syphilitic taint. The child was one of twins, the other being pale and delicate, but showing no signs of scurvy, although fed in the same way. For the first six weeks of life the child had been breast-fed, and after that was brought up entirely on Borough Council sterilised milk, according to directions and under supervision. The mother seemed to be an intelligent and careful woman.

*Condition on admission.*—A pale, fairly nourished child; weight 13 pounds. Fontanelle admitted three fingers. The tongue was furred and the mouth rather dirty. There were no teeth, and consequently no swelling of the gums. Well-marked rickety rosary and some enlargement of the epiphyses of the long bones. No indication of intra-orbital hæmorrhages. Temperature 100° F.; pulse 140; respiration 32. Heart and lungs: Normal. The liver reached one finger's breadth below the costal margin; spleen not felt. Urine: Acid; no albumin, sugar, or blood. Limbs: Both thighs and legs were very much swollen and extremely tender. The veins showed up clearly through the skin, which was tense and shiny. The swelling was more marked in the left leg, and especially well felt as a hard mass in the popliteal space. The child would not move her legs, and cried if they were touched. Arms: Nothing abnormal. An X ray photograph revealed typical large subperiosteal swellings situated at the lower ends of both femora, more especially the left, and some swelling of the shafts above; this extended to the lower end of the diaphysis on each side.

*Treatment.*—The child was given fresh milk and water in the proportion of 4:1 at intervals of 2½ hours for the first four days. Fresh orange juice (1 ounce) and raw meat juice (4 drachms) were also given daily. On May 16th undiluted milk was given in 5-ounce feeds, with sodium citrate, 6 grains, to each feed. On June 3rd the raw meat and fruit juices were stopped, and one feed of Mellin's food was allowed daily.

*Result.*—Within a week the swelling began to subside and the child made attempts to move her legs; at the end of two weeks there was free movement and no tenderness. The temperature remained irregular, rising at times to 99°. This was probably due to absorption of the effused blood. At first there was a fall in the weight to 12 pounds 14 ounces, but afterwards a steady increase to 14 pounds. X ray photographs, taken at intervals, showed a gradual decrease in the swellings. The child left the hospital on June 30th, and her condition was then very satisfactory in every respect.

*Remarks by* Dr. CARR.—The vast majority of cases of infantile scurvy occur in children who have been fed for at least several weeks exclusively, or almost entirely, either on patent foods or on condensed milk. It is, however, very important to recognise that the disease is met with,

fortunately only rarely, in infants who have been fed on boiled or sterilised milk, because if even only a very few well-marked cases occur under these circumstances, it necessarily follows that there must be a much larger number of children who suffer from slighter manifestations, the real nature of which is likely to pass unnoticed unless the possibility of the occurrence of infantile scurvy is considered.

It is easy never even to think of the possible scorbutic origin of many infantile ailments. A few years ago I was attending the infant son of a medical man who had been fed for some months, with the utmost care, on sterilised milk only. Not until the sudden occurrence of an acutely painful swelling in connexion with the right femur, followed by rapid recovery as soon as fresh milk, raw meat juice and fruit juice were given, indubitably showed the child to be suffering from scurvy, did I realise that the general malaise, the anæmia, and the slight tenderness on movement, which had been present for some time before, were merely early manifestations of the same disease. I was obsessed at the time with the idea that an infant not fed on patent foods or condensed milk was practically safe from scurvy.

We do not know as yet why so few of the many children who are fed on sterilised milk develop scurvy. Probably the essential factor is prolonged sterilisation or prolonged boiling of the milk; the danger from milk which has only just been raised to the boiling point for a very short time seems fortunately to be infinitesimal. Naturally, also, the risk is greater when extreme care is taken that the child has nothing except sterilised milk. Lastly, the occurrence of some other illness may determine the development of marked scorbutic manifestations in an infant who might otherwise escape. In the child of the medical man just referred to, an attack of influenza, followed by some middle-ear trouble, seemed to act as the exciting cause. It is interesting to note that the child whose case is here recorded was one of twins, and that the other twin—fed exactly in the same way—although delicate, appears to have escaped any obvious manifestation of scurvy. Evidently the determining factor in producing the characteristic symptoms must be a very slight one.

Another point worth noting is the possibility of mistaking a subperiosteal swelling, due to hæmorrhage resulting from scurvy, for a sarcomatous growth. This grave mistake is especially liable to occur should the swelling be one-sided, and the child still toothless so that the gums are not affected. The X ray appearances, as in the present case, may closely simulate those presented by a subperiosteal sarcoma. Although I have not myself met with this difficulty in diagnosis, I have heard of cases in which the question of amputation of the thigh has been seriously entertained for a swelling of the femur, which, from its characters and from the skiagram, was regarded as malignant, but which subsequent developments showed to be due simply to infantile scurvy.

### MEDICAL SECTION.

*Some Observations on Low Blood Pressure.*

A MEETING of this section was held on Feb. 28th, Dr. J. MITCHELL BRUCE, the President, being in the chair.

Dr. W. EDGECOMBE read a paper entitled "Some Observations on Low Blood Pressures." He said that the results of a long series of observations had been examined to determine the average level of blood pressure both morning and evening, and the average daily change to serve as a basis from which might be noted deviations consequent upon special procedures. The effect of various drugs had been tried, and as the chief object was to test whether they produced a sustained rise in blood pressure, the method of taking morning and evening readings was preferred to that of observing the immediate effect of the drug. The latter, however, was also done in certain instances. Excluding cases of acute illness with febrile disturbance—the acute specific fevers, &c.—the following were some types of disorder which frequently presented a low blood pressure: 1. Subjects with poor circulation, cold hands and feet, and liable to chilblains. Dr. Edgecombe had met with several examples in which the systolic blood pressure rarely rose above 95 mm. Hg. By means of baths, massage, and exercise a temporary rise might be effected, during the maintenance of which the objective and subjective signs of defective circulation improved manifestly; but it was difficult to effect an enduring rise in the general level of blood pressure in those cases, for they were prone, on cessation of treatment, to relapse to their former state. 2. Cases of pure neurasthenia, having as their prominent characteristic profound fatigue, either somatic or psychical, or both. Whether the low blood pressure in those cases of neurasthenia was the cause or the effect of the extreme fatigue it was not easy to say. The probable sequence of events was a lowering of blood pressure by toxic or other causes, and it was the extreme feebleness of the circulation that gave rise to the subjective sensation of intense fatigue. It was certain that a rise in blood pressure was an almost invariable accompaniment of improvement. In marked contrast to those was the irritable type of neurasthenic—the "neurotic" individual, who was frequently not a true neurasthenic, but a psychasthenic or a hypochondriac. In those cases the pulse was usually quick and irritable, and the blood pressure subject to great variation, but generally above the normal, and sometimes markedly so. 3. Tobacco poisoning. 4. In cases of dilated heart, with or without valvular disease, the pressure was usually found low, and a rise in pressure was one of the indications of the progress of the case towards recovery. 5. Fibrositis. Many examples of the so-called gouty or rheumatic manifestations of lumbago, sciatica, and neuritis showed a blood pressure somewhat below normal. 6. Phosphaturia. 7. Arthritis deformans. Contrasted with the ease with which a high blood pressure might often be reduced, the permanent raising of a low pressure was a matter of greater difficulty. Fortunately it was seldom necessary, were it possible, to raise the blood pressure to a great extent; a relatively small rise was, in most cases, coincident with marked amelioration. To effect a rise, non-medicinal measures, such as diet, exercise, change of air — for example, to high altitudes,—and hydrotherapeutic procedures were to be preferred to drug treatment. With regard to diet, an excess of meaty food should be prescribed, with a corresponding diminution of the starchy elements. Exercise, carefully graduated, improved the tone of the heart and vessels and raised the pressure; while altitude and the baths mentioned had a marked effect in the same direction. If drugs were required, pituitary extract would seem to have the most powerful and rapid effect; but Dr. Edgecombe had little or no experience of its continued use over long periods, and would rather hesitate to give much of so powerful a substance lest unlooked-for late results accrued of a harmful character. Next in potency would be caffeine, to be given only if the patient were not an excessive tea drinker. Calcium lactate appeared to be moderately effective, and strychnine was disappointing. Digitalis should be reserved for cardiac cases.

A discussion followed, in which Dr. C. O. HAWTHORNE, Dr. NATHAN RAW, Dr. F. H. HUMPHRIS, Dr. O. K. WILLIAMSON, Dr. R. HUTCHISON, Dr. F. W. PRICE, Dr. W. BEZLY THORNE, and the PRESIDENT took part, after which Dr. EDGECOMBE replied.

### BALNEOLOGICAL AND CLIMATOLOGICAL SECTION.

*The Climatic and Balneological Treatment of Neurasthenia.*

A MEETING of this section was held on March 1st, Dr. T. F. GARDNER, the President, being in the chair.

Dr. W. RINGROSE GORE (Llandrindod Wells) read a paper entitled "The Climatic and Balneological Treatment of Neurasthenia." He said: Balneological treatment, although effective in removing the cause in most cases of neurasthenia, is still only to be regarded as complementary to other methods. In no disease are the details of general treatment of greater importance than in neurasthenia. One of the most essential factors in treatment is time, and many failures result from non-appreciation of this fact. It is very important to impress this upon patients; otherwise they become unduly depressed, when a short course of

treatment fails to effect a cure. Patients in a markedly debilitated state of health require rest in bed, combined with massage and careful dieting, before being subjected to spa treatment. On the other hand, neurasthenics in whom the disease is dependent on some chronic abdominal condition, such as gall-stones, chronic appendicitis, or some abdominal displacement, should be recommended spa treatment before and not after operation. Practically all cases of neurasthenia have a toxic basis and a very large number of cases are due to, or associated with, some form of digestive trouble. It is in these cases that properly regulated spa treatment is of signal value. At Llandrindod Wells the chief treatment consists in the drinking a natural saline water every morning. The action of this water is mainly one of gastro-intestinal lavage, which aids the elimination of toxic products, the origin of which is frequently to be traced to the digestive canal. This saline, being practically isotonic with normal blood serum, is not retained in the stomach but passes through the pylorus into the small intestine almost as quickly as it is taken. Owing to the stimulating effect of the salt on peristalsis it acts as a mild aperient, but this effect is in no way debilitating, inasmuch as no flow of serum from the bowel is induced. The effect of this treatment is very rapid. The appetite increases, the digestion improves, and the patient on appropriate diet almost immediately puts on weight. There is also at Llandrindod a chalybeate spring which is prescribed for its tonic effect. The constituents of natural mineral waters have an as yet unexplained effect upon the body cells. This has been ascribed to radio-activity, but may be in some way due to a renewal of the salts in the blood by others in a more active chemical condition. The external methods of treatment at Llandrindod are common to those in practice at most spas, and great discrimination is required in their application. High-frequency currents, douches of different kinds, and reclining baths at various temperatures are all valuable accessory methods of treatment, and flushing of the colon, as practised at Plombières, is beneficial in cases where mental depression is a prominent symptom. The choice of climate depends to a great extent upon the stage of the disease and the age of the patient. In most cases a preliminary rest cure is advisable, and subsequently a stay at a quiet bracing station should be recommended. Mountain or sea air is to be preferred unless they induce insomnia. In the summer it is easy to find a suitable climate in the British Isles, but in winter difficulty arises, inasmuch as neurasthenics require an open-air life. Young patients, especially those on the road to recovery, do well at an Alpine resort so long as they are content to keep to the milder forms of exercise. A sea voyage to the West Indies provides an open-air life under agreeable conditions of temperature for elderly patients. The Italian Riviera, Pau, Algeciras, and Ronda are all suitable stations in southern Europe. Algiers is a good winter resort, and in Egypt the stations round Cairo are to be preferred to those of Upper Egypt as being more bracing.

Dr. C. W. BUCKLEY (Buxton) said that there was one important mode of treatment which was of extreme value in neurasthenia, especially if accompanied with restlessness and insomnia—namely, the cold pack at a temperature of about 90°. It was doubtful whether there was any other measure of equal value for such cases. Referring to climate, the value of sea voyages was open to doubt, except in the slightest cases, as the monotony and want of occupation tended to increase morbid introspection.

Dr. PRESTON KING (Bath) considered that in the treatment of neurasthenia change was all important, with rest, and, as far as possible, absence of worry. Physical disease, as colitis, arthritis, or affections of the heart, must be treated. In colitis the Plombières douche was useful, but it was after all only to be recognised as a glorified enema. Too much had been claimed for the latest "cure." The same might be said of the Nauheim baths. These did good in some quick pulse cases, not by virtue of some occult action of gas bubble upon the skin, but rather by the tepid bathing aided by suggestion. Properly used, suggestion was a distinct help to cure, not only in neurasthenia, but in all illness.

Dr. W. EDGECOMBE (Harrogate) regretted that the author of the paper had not defined clearly what was meant by the term neurasthenia. The more severe cases, characterised by profound fatigue, formed a well-marked group, the main factor in the treatment of which was rest. The milder cases were so ill-defined and protean in their manifestations that it was impossible to formulate definite rules for treatment. Each case must be treated on its merits; the tact and personality of the physician in charge were not the least important factors in procuring a good result.

Mr. WILLIAM ARMSTRONG (Buxton) considered that neurasthenia depended upon disturbance of the sympathetic nervous system—in some cases preceded by, in nearly all followed by, auto-intoxication. He strongly advocated direct treatment of the cervical ganglia of the sympathetic in minor cases by means of ionisation of the neck: in more severe ones by anæsthetic ionisation followed by light application of the electric cautery. For the auto-intoxication nothing was so helpful as the drinking and inhalation of strong radium emanations in water (8000 machi units per litre), which greatly increased nervous force and also strongly stimulated the excretion of waste products, especially increasing the output of carbonic acid.

Mr. W. T. REES (Llanwrtyd Wells) alluded to the fact that preceding speakers had not mentioned influenza as a possible cause of neurasthenia, but in his opinion cases of neurasthenia had been much more numerous since the advent of influenza in this country. He concurred with the previous speakers that it was desirable to have a definite conception as to what conditions should be included under the term neurasthenia. In the absence of any authoritative pronouncement on the matter, he had for himself adopted the meaning of the word, from its Greek derivatives, which signified lack of nerve force. The term neurotic, on the other hand, he had always considered as applicable to a highly excitable and unstable state of the nervous system, associated with exaggerated reflexes.

Dr. F. G. THOMSON (Bath) was of opinion that the first essential in the treatment of neurasthenia was to get a clear mental conception of the nature of the disease. Dr. Gore's statement that it was due to gastro-intestinal toxæmia was not borne out by facts. It was not the *bon vivant* who became neurasthenic, but the patient who, after years of anxiety and worry, eventually broke down under the strain. Neurasthenia was the psychosis of exhaustion, and the primary factor in treatment must be complete mental and physical rest. The great majority of severe cases were bad sleepers, and such cases were likely to derive far more benefit from a sedative than from a bracing climate.

The PRESIDENT said he had been asked to say something respecting Bournemouth and its climatic suitability for neurasthenics. He mentioned the various degrees of sedative influences exercised by central Bournemouth, the east and west cliffs, and their applicability for securing sleep. He also mentioned Bournemouth's quiet Sunday as a unique feature of this town, whereby much of the noise and unrest of other places was avoided. He agreed that much in the treatment of neurasthenia depended on the personality of the physician and the wise use he made of suggestion suited to each particular case.

## MEDICAL SOCIETY OF LONDON.

*Pathological Specimens.*

A MEETING of this society was held on Feb. 27th, Mr. CHARTERS J. SYMONDS, the President, being in the chair.

Dr. F. J. POYNTON showed a Heart from a case of Rheumatic Carditis. The visceral pericardium showed the usual shaggy appearance of rheumatic pericarditis. Upon the aortic valve there were minute vegetations, but connected with the mitral valve springing from chordæ tendineæ there was a large vegetation such as is found in malignant endocarditis. The specimen accordingly supported the view maintained by Dr. Poynton that acute rheumatism was an important cause of malignant endocarditis, which was not, in his opinion, always an evidence of a secondary infection in the rheumatic. Another remarkable feature in the case was a pericardial exudation close upon a pint in quantity and blood-stained. The illness occurred in a boy of 7 years who had been ailing indefinitely for two weeks and then developed multiple arthritis. That subsided in three days, when he was allowed to get up. A rheumatic rash appeared, and he was admitted with carditis seven days after the first appearance of arthritis and died six days later from syncope. The rare feature of bulging of the

præcordial intercostal spaces was noted two days before death. There was left pleurisy with effusion. A blood culture during life was not obtained, although the attempt was made. The diplococcus was present in the vegetation near the mitral valve. The specimen resembled the severe experimental carditis that was produced in a rabbit by a virulent intravenous inoculation of the diplococcus. A photograph was published in THE LANCET of Sept. 29th, 1900. The specimen showed also a chorda tendinea. At the same date as the case he now recorded a fatal case of rheumatic pericarditis occurred also at the Hospital for Sick Children, Great Ormond-street. The diplococcus was isolated in pure culture by Dr. J. G. Forbes, the clinical bacteriologist to the hospital, and a subculture was shown.

Dr. POYNTON also showed specimens from a case of Acute Leukæmia in a girl aged 17 years. The total duration of the illness was five weeks. The patient thought at first she had a bad cold with sore throat and swelling of the glands in the neck. She actually continued at her work until Jan. 2nd, and died on the 18th. Between the onset and her admission to hospital the following additional symptoms developed: anæmia, fungating swellings of the gums with great fœtor, and continual oozing of blood. Ulceration of the palate. Weakness and purpura. The specimens showed the fungating gums, a large thymus, petechiæ in the gastric muscle, the marrow in the femur greyish in colour and semi-transparent, and the spleen slightly enlarged.

Mr. A. E. J. BARKER showed the following specimens: 1. Primary Carcinoma of the Cæcum, with a secondary nodule in the sigmoid flexure. ? Implantation from the upper cæcal growth. 2. Carcinoma of the Lower Rectum, with another smaller cancerous ulcer four or five inches higher up. ? Extension along the submucous lymphatics in the sense of Sampson Handley's infection. 3. Extensive Tubercle of the Colon (Hepatic Flexure) removed by operation.

Mr. ERNEST H. SHAW showed six specimens: 1. A case of Carcinoma of the Right Kidney in which there was a large lobulated hæmorrhagic tumour with an elongated flattened kidney stretched over one side of it. The tumour weighed 76 ounces; it was removed by operation from a man, aged 22 years, who had noticed a swelling in the right loin for nine years. Microscopical examination showed a collection of large cells, many of which were vacuolated. In places the cells were arranged in the form of tubules exactly like the tubules seen in a kidney. 2. A case of Carcinoma of the Œsophagus with Secondary Growths in the Liver. There was a large ulcerating growth occupying the œsophagus at about the level of the bifurcation of the trachea. The specimen was from a man, aged 31 years, who presented no symptom of obstruction during life. There was an indefinite history of hæmatemesis occurring about a month before death. Secondary growths were found in the liver and lymphatic glands of the neck, mediastinum, and abdomen. Microscopically the growth was found to be a columnar-celled carcinoma. 3. A case of Columnar-celled Carcinoma of the Liver Secondary to the Œsophagus, the liver weighing 179 ounces. 4. A case of Carcinoma of the Œsophagus Invading the Trachea. There was a large ulcerating growth seen at the middle of the tube extending through the trachea just above the bifurcation. A rod passed through an opening from one tube to the other. The adjoining lymphatic glands were affected by secondary deposits. The specimen was from a man, aged 53 years, who died with septic broncho-pneumonia. 5. A case of Chronic Nephritis affecting a rudimentary left kidney. Both organs were white, firm, and markedly granular. The nephritis was of the glomerular type (contracting white kidney). The organs were from a woman, aged 32 years, who died with infective endocarditis of mitral and aortic valves. She also presented the following lesions: arterio-sclerosis, chronic or old pleurisy, gout, and reducible inguinal hernia. 6. A case of Calcareous Degeneration of the Aortic Valve with Two Segments. There was atheroma of the coronary arteries. The heart weighed 15½ ounces. The left ventricle was dilated and the wall hypertrophied. The left coronary artery showed marked atheroma and narrowing of its lumen. The specimen was from a man, aged 67 years, who died suddenly.

Dr. F. PARKES WEBER showed specimens from a case illustrating the occurrence of prolonged or fatal syncopal attacks in elderly persons. The patient, a rather stout, flabby-looking man, aged 58 years, was admitted to the German Hospital on Dec. 7th, 1910. He had been much exposed to great heat owing to his work as a baker. Six weeks before admission, after an hour's walk, he was suddenly seized with a prolonged syncopal attack. From that time he remained very feeble, had a very weak pulse, and kept to his bed. In the hospital, although the heart's action improved somewhat under treatment, the gangrene progressed, the left leg as well as the right one becoming affected. Both legs showed discolouration up to the knees, the temperature was septic in type, and on Jan. 6th, 1911, the patient died. At the necropsy the coronary arteries were found sclerosed, and in the descending branch of the left coronary artery the channel appeared completely closed. There was much athero-sclerosis of the aorta with an atheromatous ulcer just distal to the origin of the left subclavian artery. In all probability in this case the prolonged syncopal attack with which the final illness commenced, coincided with the sudden complete closure of a portion of one of the already diseased coronary arteries.

Dr. R. C. JEWESBURY showed a heart with Tricuspid and Mitral Stenosis. The tricuspid valve was markedly stenosed, the edges of the septal and infundibular cusps were quite adherent, the edges of the septal and marginal cusps partially adherent, leaving a "button-hole" opening admitting only one finger, the edges of the valve being considerably thickened. The left ventricle was stenosed.

Dr. JEWESBURY also showed a Dilated Œsophagus from a man aged 34 years. The dilatation was uniform throughout its length except at its lower portion where it joined the stomach; that portion was more contracted than normal and would only admit the tip of the small finger. Fluids, however, readily passed through it. As well as being dilated the œsophagus was considerably increased in length; that caused it to deviate laterally from its normal course, and the lower end was directed to the left after it had been crossed by the aorta.

The PRESIDENT showed the following specimens: 1. A specimen from a case of Acute Cholecystitis removed about two weeks after the onset of the attack from a man aged 52 years; it contained a single calculus. A small piece of liver was seen attached to the specimen. The patient recovered without escape of bile. 2. A Gall-bladder containing a solitary stone; there was thickening of the wall. There had been several attacks of cholecystitis. The specimen was from a woman aged 42 years. There was recovery without any escape of bile. 3. A Gall-bladder showing patches of gangrene. The specimen was removed from a man, aged 70 years, who was taken ill on Feb. 7th, 1910, with vomiting, pain, and collapse. The operation was on March 3rd. The recovery was rapid without any escape of bile. There were no calculi in the case. 4. An unusually large Gall-bladder removed from a woman of 43 years. The hepatic surface showed a gangrenous appearance. The gall-stones removed from the gall-bladder were also shown. The patient was taken ill with pain, vomiting, and diarrhœa. There was no history of any previous illness or pain. The gall-bladder reached to the level of the iliac spine. A large stone was impacted in the sacculus seen at the lower end of the gall-bladder and so closed the cystic duct.

Dr. H. M. TURNBULL showed cases of Mesaortitis, apparently an isolated syphilitic manifestation in father and daughter; Mesaortitis in a child aged seven years; Ectopic Chorion Epithelioma.

Mr. T. B. LAYTON showed a specimen of Ununited Fracture of the Tibia and Fibula. He also showed a specimen of Carcinoma of the Skin complicating an Osteomyelitis of the Tibia. The patient, aged 39 years, had fallen 25 years ago. Soon after a large swelling of the leg appeared. Much bone had come away from the wound in the course of time. The limb was amputated below the knee. Microscopic sections showed the condition was carcinomatous.

Mr. LAYTON also exhibited a specimen showing Senile Atrophy of Bone, Fibrous Union of a Fracture of the Femur, and Fibrous Ankylosis of the Knee-joint.

Mr. P. MAYNARD HEATH communicated a case of a Cyst of the Upper Extremity of the Femur. The patient was a boy who was admitted to hospital on Oct. 28th, 1909. One year previous he had fallen and hurt himself in the left groin. Three months later he fell again and broke the neck of his left femur. He was treated

in plaster-of-Paris and had never walked well since. On the day before admission he fell and again broke his femur. On Nov. 17th, 1909, the head of the femur was removed from the acetabulum, as it appeared too small to serve any useful purpose. The upper extremity of the femur was then pushed up into the acetabulum and held in position by a silver wire. The boy was kept in a double Thomas's hip splint for six months. He was now wearing a high boot and walking without crutches.

Mr. HEATH also showed a Post-anal Tumour (? teratoma) from an infant aged nine days. The tumour grew from the cleft between the buttocks just behind the anus and slightly to the right of the middle line by a narrow pedicle. The tumour consisted of a rounded skin-covered mass with two nipple-like processes. It was very soft and elastic.

## MEDICAL SOCIETY OF LIVERPOOL.

*Lepra.—The Rôle of Reflex Inhibition.—Exhibition of Case.*

A MEETING of this society was held on Feb. 23rd, Dr. T. R. BRADSHAW, the President, being in the chair.

Dr. FRANK H. BARENDT read a note on Lepra and exhibited a patient showing the macular type. After having briefly alluded to the nomenclature and history of leprosy, its endemicity in Great Britain during the Middle Ages, he showed on the screen a typical case of the nodular type, and contrasted the two forms of the disease. The patient, by birth a Scotsman, acquired the disease a year ago in South Africa. He first noticed a large anæsthetic patch on the anterior surface of the right thigh, and in the course of six months there appeared patches varying in size in the following sites: right malar region, right side of the nose, chin and lower lip, left pinna, cubital regions, both hypothenar surfaces and gluteal regions. He complained of pain and tingling in the affected areas. In October last he was admitted to the tropical ward of the Royal Southern Hospital under the care of Professor Ronald Ross. Nastin had been administered but with no beneficial result. Locally X rays had been used, especially to the right thigh, the site of the initial patch, and here a distinct improvement was noted, leucocytosis was being produced and nastin would be resumed and the results reported later.—Dr. K. A. GROSSMANN said that the appearance of the patient was not at all that generally met with in the macular form of leprosy. In his experience the colouring of the spots had never been such a deep reddish tint; in the white race they had been pale, mostly towards pink and purple; in the dark races pale, even to white. Nor had he ever seen such a swelling as the coloured part of the lower lip showed. It hardly looked like a mixed form of macular and nodular leprosy. As to treatment, he felt inclined to suggest in this case mercury in large doses.

Professor C. S. SHERRINGTON read a paper on the Rôle of Reflex Inhibition. He said a distinction was drawn between the inhibition which acted upon the skeletal muscles and that which acted on other muscles such as the heart, intestine, and blood-vessels. In these latter cases the muscles were supplied with two kinds of nerves, excitatory and inhibitory, both nerves issuing as efferent from the central nervous system. In the case of the skeletal muscles no efferent inhibitory nerve was provided but only an excitatory efferent—namely, the ordinary motor nerve. But nevertheless inhibition played an even more potent and extensive rôle in controlling skeletal muscles than it did in regard to any other kind of muscle. Its mode of action was, however, always reflex, and it inhibited the muscle by inhibiting the histo-neurone which actuated the muscle. The main purposes which this reflex inhibition served in its control of skeletal muscles were as follows: 1. It cut short the contraction of one set of muscles when another set was called into play. It thus helped, and indeed was an essential factor for, the transition from one reflex action to another. It also guarded and maintained a reflex already in operation by preventing its being interrupted by other stimuli which would disturb it; it did so by inhibiting the influence that those stimuli would otherwise produce on the nerve centres. 2. It graded the degree of intensity of the discharge from nerve centres by diminishing it to any required extent. When two afferent nerves, one excitatory and the other inhibitory, were concurrently stimulated their effects could be so adjusted as to algebraically sum. In this way inhibition made itself apparent as a graduated moderating influence by which the required discharge from any motor centre could be adjusted with delicacy to any required intensity. 3. Reflex inhibition exhibited itself in the taxis of a number of important reflexes, such as those of stepping and respiration and eyeball movements in a form in which, while the protagonistic muscle contracted the antagonistic relaxed, the relaxation being due to central inhibition of the histo-neurones of the latter. This applied apparently universally to true antagonists, but not to pseudantagonists. Pseudantagonists were dealt with by identical innervations. 4. Inhibition was the main means by which rhythmic reflexes were produced; this occurred in the following way; to take, for instance, the rhythmic reflex of stepping. One phase of the rhythmic reflex was excited, and then its very execution produced a stimulus which evoked a reflex inhibition, cutting that phase short and interrupting the action of the stimulus which excited it; the inhibition then was removed in virtue of the movement which caused it having under the inhibition lapsed. The original stimulus thus became operative again. And so the rhythmic reflex was maintained, rhythmically repeated inhibition being a main factor in its production. 5. Inhibition was followed on its withdrawal by a great augmentation of activity of the inhibited centre. This was called post-inhibitory rebound. This post-inhibitory rebound is responsible for one of the two phases of various diphasic reflexes, such as stepping, mastication, respiration, &c. Post-inhibitory rebound was very weak and irregular when the afferent nerves of the muscles had been destroyed. In other words, in tabetic muscles or rather in tabetic spinal centres the normal rebound occurred feebly or not at all. In the tabetic patient its place had to be taken by voluntary effort. 6. The drug strychnine had as its peculiar effect the conversion of reflex inhibition into excitation. Tetanus toxin and rabies virus had the same effect. These agents, therefore, worked havoc with the elemental coördination of the skeletal muscles, changing reciprocal innervations into identical innervations. Hence in tetanus patients the greater the effort made to open the jaw the more tightly was the jaw closed, and in the hydrophobia patient the greater the attempt made by the sufferer to inhibit his inspiration in order to swallow the deeper and more prolonged the inspiration which, contrary to his desire, ensued, inhibition being converted by the virus into excitation.

Dr. C. J. MCALISTER showed a patient suffering from Tabes, who had been treated by salvarsan with much benefit. The patient had acquired syphilis six years ago, the symptoms of tabes being first noticed four years ago. These were lightning pains, marked unsteadiness in gait, nocturnal incontinence, loss of the knee-jerks, &c. In one eye there was old iritis, in the other iridioplegia, and there were tertiary ulcers on the side. On Jan. 19th salvarsan was given intravenously. The injection was followed by some transitory constitutional disturbances, but manifest improvement. The pains, ataxia, and incoördination were greatly relieved, also disturbance of sensation was less marked, and the patient was able to walk a considerable distance.—Dr. A. GORDAN GULLAN was not surprised at the improvement, since many cases of the disease were greatly benefited by mercury, if this was given in the early stages and continued for a long period.—Dr. W. B. WARRINGTON briefly mentioned the very divergent views which were held on the question of the antispecific treatment of tabes.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on March 2nd, Dr. F. Hinds, the President, being in the chair.—Mr. H. H. Taylor showed a Skiagram of a Piece of Steel from an instrument in the Eye of a patient on whom he had had to perform excision. He remarked that in his experience of eye accidents the foreign body was always from the instrument, not from the substance against which the instrument struck, and he also commented on the great rapidity with which the eyeball became inflamed in these cases.—Mr. W. Barrington Prowse showed: (1) Skiagrams of some Fractures at the Wrist, which showed that the styloid process generally was broken in cases of Colles's fracture; (2) a case of Scoliosis in a girl aged 10 years, which had started at three years of age; (3) a Stone in the Bladder which had not been detected by sounding; (4) a case of Deformity

of the Knee due to tuberculous disease; (5) Unerupted Canines; and (6) a case of Gastroptosis in which the colon and stomach were outlined by bismuth.—Dr. H. Nethersole Fletcher showed a photograph of a man from whom he had removed a large ulcerating lipoma, weighing 6½ pounds, from the scapular region. It had been suspected to be malignant, but this was not so.—Dr. R. J. Ryle showed two cases, brother and sister, with Upward Dislocation of the Lens, on whom he had performed needling.—Dr. Walter Broadbent showed a man with an Aneurysm of the Aorta, who had come to him simply complaining of difficulty in swallowing. If a bougie had been passed it would probably have perforated the sac. There was marked pulsation to the right of the sternum in the second and third spaces.—Dr. C. F. Bailey exhibited skiagrams of: (1) Stone in the Ureter; and (2) Osteo-arthritis of the Knee, showing calcification of the synovial membrane.—Dr. A. J. Hutchison read a paper on the Nystagmus Tests for Examining the Functional Activity of the Semicircular Canals. He described the rotatory, caloric, and pressure tests, remarking that the caloric was the most generally applicable. He entered into the diagnosis between labyrinthine and cerebellar disease by means of these tests, stating that at present the whole subject was chiefly of interest to otologists, and that even in otological cases the tests must be taken along with other and better-established methods of examination, and that they should be very well marked if much weight was to be attached to them. They would, he thought, prove to be of considerable value (1) in examining patients before performing mastoid operations for chronic middle-ear suppuration by enabling an opinion to be formed as to whether the suppuration was limited to the middle-ear or had opened into the labyrinth; (2) whether it had destroyed the vestibular apparatus or not; (3) whether it had spread beyond the labyrinth or not; and (4) sometimes they might be useful in confirming a diagnosis of nerve deafness. He concluded by remarking that the whole subject was yet young, and it was probably too soon to state what were the limitations and what were the possibilities of development of this new method of diagnosis.—Dr. A. G. Bate read a paper entitled "The Ductless Glands in Action and Interaction." The chief facts to which he drew attention were as follows. In the anatomy of the glands, the striking arrangement of the pituitary, thyroid, parathyroids, all as outgrowths of the branchial region; the differentiation of each set of glands into two divisions which are anatomically in juxtaposition, but are of different origin, function, and histology; the existence of a chromaffin system in connexion with the sympathetic, of which the medulla of the adrenals forms a part; the histological similarity of the thyroid, parathyroid, and adrenal glands with different parts of the pituitary. In connexion with the physiology of the glands, the relation of some of the ductless ones to the metabolism of different elements, the thyroid to iodine, the parathyroid to calcium, and the pituitary to phosphorus, was commented on, and clinically the vital importance of each of the ductless glands and their connexion in pathology, each one with a separate and serious disorder of metabolism, was insisted on.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Feb. 21st, Dr. W. Mitchell being in the chair.—The following specimens and cases were shown:—Dr. F. W. Eurich: (1) Microscopical demonstration; (2) specimens from a case of Gastro-intestinal Anthrax; and (3) Purulent Meningitis.—Dr. T. Jason Wood: (1) Multiple Vesical Calculi; (2) a Large Gall-stone; (3) Unruptured Tubal Gestation; (4) Malignant Growth of Colon (two specimens); and (5) Fibroid Uterus.—Mr. J. Basil Hall: Fibroid Uterus with Carcinoma of Rectum.—Dr. S. Lodge: A case of Locomotor Ataxy with Cervical and Lumbar Involvement.—Dr. Eurich read notes of some cases of Hysteria simulating Dementia.

THE INTERNATIONAL HYGIENE EXHIBITION, DRESDEN, 1911.—Sir T. Vezey Strong, the Lord Mayor of London, has consented to become the President of the British National Committee for this Exhibition, and has issued an appeal for subscriptions towards the erection and equipment of a British Pavilion. Of the £10,000 required for the purpose over £5000 has already been subscribed. Cheques should be sent to Lord Ilkeston, the treasurer, 47, Victoria-street, London, S.W.

# Reviews and Notices of Books.

*A Text-book of Medicine.* By G. DIEULAFOY, Professor of Clinical Medicine at the Faculté de Médecine de Paris, Physician to the Hôtel Dieu; Membre de l'Académie de Médecine. Authorised English Translation from the fifteenth edition of "Manuel de Pathologie Interne," by V. E. COLLINS, M.D. Lond., M.R.C.S. Eng., L.R.C.P. Lond., and J. A. LIEBMANN, Ph.D., M.A., LL.D. In two volumes. London: Baillière, Tindall, and Cox. 1910. Pp. 2081. Price 25*s.* net for the two volumes.

A TEXT-BOOK on medicine by so distinguished a clinician as Professor Dieulafoy should be of special interest and value, not only as representative of French teaching on medicine, but also as the work of a physician of wide experience. The esteem in which this book is held in France may be judged when it is seen that this translation is made from the fifteenth French edition. It has, moreover, been translated into several other European languages. In a preface specially written for the English edition Professor Dieulafoy expresses his satisfaction at seeing his work translated into English. He also pays a tribute to the contributions of English workers to the advancement of medicine, and states that, following the example of his venerated master Trousseau, he has often dipped into English medical literature. This is a modest way of stating the position. It is obvious that Professor Dieulafoy has a wide knowledge of English medicine and the views of British authorities are often quoted. At the outset we may affirm that this book is a most useful one and the translators have performed a notable service in rendering it available in readable English.

The tendency in modern text-books of medicine is to describe in detail the general characters of diseases in systematic or categorical arrangement, whereas the older text-books, such as those of Trousseau and Watson, were written in descriptive style and were truly works on clinical medicine, since the characters of the disease were illustrated by special cases rather than by collected summaries of many cases elevated into an abstraction. Professor Dieulafoy's method combines both of these methods, since, although the systematic method is adopted as the general basis, the symptoms are often brought out descriptively by means of real or hypothetical instances. This gives a somewhat original and at the same time an attractive character to the book, rendering it easy to read.

The first volume commences with the consideration of diseases of the respiratory system, which are dealt with under their appropriate headings, often at considerable length. Syphilitic affections of the nose, larynx, trachea, and lung are described in much more detail than is usual in systematic works on medicine in this country. In connexion with pulmonary syphilis Professor Dieulafoy differentiates no less than six different forms and quotes illustrative cases. In a suspected case of pulmonary tuberculosis in which, after repeated examinations of the sputum, the tubercle bacillus is not found, he strongly urges the application of antisyphilitic treatment. In describing diseases of the lung less stress is laid upon primary congestion of the lungs than is often the case in French text-books, but Professor Dieulafoy differentiates a condition which he terms inflammation of the chest. In this disease, which does not find a place in our nosology, he states that hyperæmic and inflammatory elements are differently combined, and that the lung, bronchi, pleura, and muscular walls of the thorax may all be involved. It must be confessed that the description given is not convincing, and Professor Dieulafoy himself mentions that Grasset regards this supposed clinical entity as an

attenuated pneumococcal infection. The descriptions given of the forms of pulmonary tuberculosis are very full and interesting, although the terminology even in the translation is somewhat different to that commonly in use in this country. The word phthisis, for example, indicates the last phase of tuberculous lesions in general. In regard to treatment, the use of tuberculin is dismissed with brief consideration and its employment condemned. No mention is made of its administration in small doses or of its control by opsonic methods. An interesting section is that devoted to what is called false tuberculosis of the lung, which contains a valuable description of pulmonary aspergillosis. Hydatid cyst of the lung is also discussed at some length, together with its diagnosis and treatment. The expectoration of cartilaginous, bony, and calcareous bodies is elevated to the dignity of a special section under the title of broncho-pulmonary lithiasis, and the occurrence of crises of bronchial or pulmonary colic is described. Diseases of the pleura have been the subject of special research on the part of Professor Dieulafoy and, as might have been expected, they are described with admirable clearness and in exhaustive fashion. The descriptions of sero-fibrinous pleurisy and of the indications for paracentesis are masterly and authoritative. The characters of hæmorrhagic pleurisy are described and four different groups are separated with different causation. The difficult subject of interlobar empyema is dealt with fully, and some valuable information is given in regard to the clinical characters of this condition and its diagnosis. A separate form of pleurisy is described under the heading of mediastinal pleurisy.

The section on diseases of the heart calls for but little comment. The subject is treated upon ordinary lines and the descriptions given are clear and practical. Little or no reference is made to recent work upon His's bundle and upon the complex question of arrhythmia. Aortic stenosis is but briefly and inadequately described, and in connexion with tricuspid regurgitation it is a little surprising to find reflex spasm of the pulmonary vessels given as a cause of functional inefficiency of that valve. The treatment of valvular lesions is fully considered, and the recommendations given are characterised by their practical and useful nature. Exophthalmic goitre is included among neuroses of the heart, and a long and interesting account is given of this condition. Professor Dieulafoy concludes in regard to treatment that it is impossible at present to give surgical measures the preference over medical.

Diseases of the digestive system occupy nearly half the first volume and are dealt with in the exhaustive and original manner which characterises Professor Dieulafoy's work. It is impossible to do more than refer briefly to some of the special features of this section. The subject of diphtheria is treated at great length, and the importance of a bacteriological diagnosis in every case is urged. There is an interesting description of other membranous exudates in the pharynx, including those due to Brisou's coccus, streptococci, staphylococci, pneumococci, the colon bacillus, micrococcus tetragenus, and syphilis. Appendicitis and its numerous complications are treated exhaustively. In regard to the pathogenesis of this condition Professor Dieulafoy maintains that it results from "the transformation of part of the appendicular canal into a closed cavity, which becomes a focus of infection and intoxication, due to the increased virulence of the imprisoned microbes." He is insistent in urging immediate operation in all cases of appendicitis, and most strongly condemns waiting for a quiet interval. On the other hand, he is careful to discuss conditions of pseudo-appendicitis in which operation is unnecessary. A clear and full account is given of hypertrophic tuberculoma of the cæcum, and some interesting cases of this condition are recorded. In connexion with diseases of the peritoneum, various forms of primary peritonitis, notably those due to the pneumococcus and the streptococcus, are described. The subject of cirrhosis of the liver is dealt with in a lucid and interesting manner, and an interesting section deals with the curability of this condition and of the associated ascites.

The second volume commences with the study of diseases of the urinary system. The subject of nephritis and its varieties is discussed at some length, and the various views given in regard to their etiology and pathology are carefully outlined. Professor Dieulafoy describes a form which he calls toxic appendicular nephritis. The surgical treatment of nephritis is carefully discussed in an interesting section. Renal syphilis and renal calculi are fully and carefully described. Reference is made in connexion with the symptoms of large fixed calculi in the kidney to the description by Sydenham of his own symptoms.

Diseases of the nervous system are next dealt with. These are well classified and are described in clear and simple fashion. Many illustrative cases from the practice of Professor Dieulafoy and his colleagues are given in more or less detail, and authorities are frequently quoted. In connexion with aphasia, the various forms of this condition are described on conventional lines, and then the new doctrine in regard to aphasia as introduced by Marie is described. One section is devoted to a discussion of the medico-surgical errors in regard to cerebral localisation. It is maintained that there is no symptom or sign to enable a differentiation to be made between Jacksonian epilepsy due to a lesion of the Rolandic area, or to one of the frontal region. Under the general heading of neuroses, hysteria is described in some detail; also a condition to which the name of cerebro-cardiac neuropathy, or Krishaber's disease, is applied. The subject of tetany is dealt with very briefly, and the rather heterodox suggestion is made that some cases may be due to Nicolaier's bacillus.

General and infectious diseases are discussed under the following headings: Eruptive Fevers, Typhoid Diseases, Infectious Diseases Proper to Man, and Infective Diseases Common to Man and Animals. Diseases of the spleen are described next and then the pathology of the blood. Under the heading of Chlorosis, a condition called by Professor Dieulafoy chloro-Brightism is described. It appears to consist of the ordinary symptoms of chlorosis, together with puffiness of the face, œdema of ths eyelids, dead fingers, epistaxis, and cramps in the calves. It is affirmed that a rigid milk diet is of great value in the treatment of such cases. Rheumatic and dystrophic diseases are next discussed. This section contains a very full account of diabetes and its treatment. Under the heading of Parasitic Infections only trichinosis and filariasis are described. Diseases affecting the locomotor system, venereal diseases, and the intoxications occupy the concluding sections. There are also three small appendices dealing with special forms of treatment.

Professor Dieulafoy's book affords an interesting presentation of French practice in medicine and is well worth study. We have read it with great interest, as it is both original and suggestive, and it must be helpful to the practitioner, since it is especially calculated to afford light in regard to obscure and rare cases.

---

*A Text-book of the Practice of Medicine.* By JAMES M. ANDERS, M.D., Ph.D., LL.D., Professor of Medicine and Clinical Medicine at the Medico-Chirurgical College, Physician to the Medico-Chirurgical Hospital, Philadelphia. Illustrated. Ninth edition. London and Philadelphia: W. B. Saunders Company. Pp. 1326. Price 24s.

A WORK which has reached the ninth edition needs no preface from us as to its nature and scope; suffice it to say that the book is intended to introduce the student to the present state of the knowledge of the practice of medicine

in general and of the diagnosis, differential diagnosis, and treatment of disease in particular.

The aim of the author in producing a new edition is to add the most important practical advances since the date of the previous issue, at the same time much of the text that has become more or less obsolete has been eliminated, thus obviating any material increase in the size of the volume. Controversial points have been, for the most part wisely, omitted from consideration, and the author has dwelt in detail on the practical aspects of medical affections which are most likely to aid practitioners and students in diagnosis and treatment. As this work is naturally intended mainly for American students, the section on tropical diseases has been somewhat enlarged, so as to meet the steadily increasing need of knowledge in this branch of internal medicine. Among the conditions and diseases newly discussed in this volume are: filaria Philippinensis, chronic purpura, leucanæmia, acute pneumonokoniosis, hereditary cerebellar ataxia (Marie and Nonne), myatonia congenita, and adiposis tuberosa simplex. New and "rewritten matter" also includes the following: The action of Flexner's and Wassermann's serum in the treatment of cerebrospinal meningitis, Kelling's method or the hæmolytic serum test in gastric carcinoma, certain new theories on the causes of uræmia, traumatic neuroses, and symptoms of combined system sclerosis. Numerous other subjects receive brief attention, so that the work has been thoroughly brought up to date.

This text-book is complete in all respects; if it possesses no marked superiority over others published in America or in this country, it does not fall behind the best of them.

---

*Pathological Anatomy Plates.* Reproduced from fresh preparations. With explanatory anatomical and clinical text by ALFRED KAST, M.D., Professor of Clinical Medicine, Hamburg; formerly Director of the Hamburg State Hospitals. Assisted by EUG. FRAENKEL, M.D., Professor of Anatomy, General Hospital, Hamburg-Eppendorf; and THEODOR RUMPEL, M.D., Senior Physician, General Hospital, Hamburg-Eppendorf. English translation by FRANCIS C. PURSER, M.D. Dub., F.R.C.P. Irel., Assistant Physician, Richmond, Whitworth, and Hardwicke Hospitals, Dublin. With Preface by J. LORRAIN SMITH, M.D. Edin., Professor of Pathology, University of Manchester. Complete in 26 parts. London: Baillière, Tindall, and Cox. 1910. Price 5 marks per part; single plates, 1.50 marks.

THIS work consists of a large number of plates illustrating the appearances of fresh specimens of the common abnormal conditions of the various systems and organs of the body. It is published in 26 parts, each containing from four to six plates, with explanatory notes in German, English, Italian, and Russian. These notes comprise in most cases brief clinical records of the cases from which the specimens were derived, with a description of the post-mortem appearances, and more or less full details in regard to the particular morbid condition shown.

In a few of the plates there are representations of the histological characters of the chief lesions, but for the most part only gross changes are illustrated. The plates are reproduced in colour and are of a high level of attainment as examples of colour printing, since they reproduce with striking fidelity the appearances of post-mortem specimens recently removed. The subjects selected for illustration are also well chosen and comprise examples of pathological conditions affecting the circulatory organs, the osseous system, muscles and tendons, the nervous system, the intestinal tract and peritoneum, the liver, pancreas, spleen and lymphatic glands, the respiratory system, the urinary organs, and the sexual organs. A few rare conditions are included; for example, the appearance of an exanthem in a case of cholera, though since this is the only lesion of the skin which is represented it is a little difficult to understand why it is given. It is also not quite clear to us why an accessory thyroid at the root of the tongue is described under the heading of organs of special sense, and why even if it is so regarded it should be the only representative of these organs to be illustrated. An uncommon condition shown in one plate of the urinary organs is malakoplakia of the bladder. Several good plates illustrative of rickets and infantile scurvy are given, the latter condition being referred to as Möller-Barlow's disease. We have no affection for proper names applied to diseases, and when this terminology is made a battle-ground of priority claims it becomes not only clumsy but irritating.

All the plates are good and we do not single out individual examples for special commendation. In the majority of cases the organs are represented of the natural size, but in a few instances they are slightly reduced. The only description attached to each plate is the name of the condition and of the organ affected in Latin, with a reference letter and number to correspond with the letterpress. If there be a need for an atlas of pathological anatomy this work is well adapted to supply it, but the objection to atlases and plates applies to this one—viz., the danger that the student may rely upon his study of these pictorial representations, which are admittedly admirable in the present instance, instead of using them as a companion to his work in the post-mortem room. A study of morbid anatomy involves other considerations than those of mere naked-eye appearances, such as texture, consistence, and relation to other organs, which no atlas can supply, and even museum specimens are only a poor substitute. As a means of revision before examination, or to recall appearances to practitioners with limited opportunities for post-mortem work, this atlas may be useful, but a little post-graduate study in the post-mortem room is of greater value than prolonged examination of plates, excellent though they are.

*Practical Bacteriology, Blood Work, and Animal Parasitology, including Bacteriological Keys, Zoological Tables, and Explanatory Clinical Notes.* By E. R. STITT, A.B., Ph.G., M.D., Surgeon, U.S. Navy; Graduate, London School of Tropical Medicine; Associate Professor of Medical Zoology, Philippine Medical School; formerly Instructor in Bacteriology, and Tropical Medicine, U.S. Naval Medical School. Second edition, revised and enlarged, with 91 illustrations. London: H. K. Lewis. 1911. Pp. 345. Price 6*s.* 6*d.* net.

IN our review of the first edition of this book[1] we anticipated that owing to the extremely practical character of the work it was likely to be of service to very many practitioners. This proves to have been the case, for in less than two years this second edition has been called for. The book is founded on the author's experience gained by submitting the methods advised in it to the criticism of a large number of post-graduate workers while under instruction at the American Naval Medical School. Such methods, and such methods only, as were found to be adapted to the requirements of practical, speedy, and satisfactory clinical laboratory diagnosis have been adopted. Apparently this same body of practical surgeons has decided that the usefulness of the work would be increased by the addition of a section dealing with the chemical examination of the urine and of the gastric contents.

A glance at the title shows what a large amount of ground this small manual of some 340 pages essays to cover. By keeping, however, within certain well-defined limits, Dr. Stitt has produced a work of real value. It is not a book for the

[1] THE LANCET, June, 1909, p. 1604.

student, but for one already trained in laboratory technique, and it will be especially valuable to all those who, in the colonies, or in the various services, have to practise without means of ready access to well-filled book-shelves. It should be of use also to those who have to deal with the problems of tropical disease. When the various suggestions made to meet the problem of the overcrowded curriculum are carried out it will be with this type of work, we suppose, that the medical student of the future will be supplied.

In this edition there is no change in the arrangement of the subject-matter, and "keys" or classifications form an essential feature of the work. There have, however, been a good many additions and a thorough revision of the work; it is not a mere reprint. The illustrations have been increased in number, and the spirit of classification found in the text is met with here also. The section on animal parasitology has been rewritten and almost doubled, and a chapter on poisonous snakes, with illustrations, has been added. The increasing importance of the protozoa leads to the inclusion of methods of cultivating and staining these organisms. The chapter dealing with fixation of complement and the methods based on this fixation has been increased, and the phenomena of anaphylaxis now find a place. There are additions, too, in the blood section of the book. A useful new illustration is given of the wing venation in tabanus, stomoxys, and glossina; and in the section on urine there are diagrams of the chief absorption bands.

The book is, as we have indicated, a useful and accurate practical manual, and is well printed and illustrated.

---

*Manual of Bacteriology.* By ROBERT MUIR, M.A., M.D. Edin., F.R.C.P. Edin., Professor of Pathology, University of Glasgow; and JAMES RITCHIE, M.A., M.D. Edin., F.R.C.P. Edin., Superintendent of the Royal College of Physicians Laboratory, Edinburgh, formerly Professor of Pathology in the University of Oxford. Fifth edition. With 170 illustrations in the text and 6 coloured plates. London: Henry Frowde and Hodder and Stoughton. 1910. Pp. 688. Price 10*s.* 6*d.* net.

WE welcome this new edition of the Manual of Bacteriology. Probably no other work in English is more firmly or deservedly established as the text-book on its subject for the use of the medical student and practitioner. The book is, of course, of service to a wider circle than this, but it is as a work by medical men for students of medicine that it is especially valuable.

It is only three years since the last edition was published,[1] but much progress in bacteriology has been made during this period, and the results are incorporated in the present issue. Once more, too, this feat has been accomplished without any undue increase in the volume. Some 80 pages have been added, and there are four additional illustrations, but the bulk of the volume remains substantially unchanged. New editions do not always deserve to be so-called, but in the present instance it is literally true that there is hardly a chapter which remains unchanged, and in many cases the alterations are very considerable and have involved recasting the entire section. Not only is new information added, but the much more troublesome task of modifying the argument in the light of the new information has not been shirked. In the earlier chapters, dealing with the general biology of microbes and with methods for their study, the matter has been arranged somewhat more logically and systematically. The formulæ of various new special media, such as Martin's gonococcus medium, that for the culture of the bacillus of whooping-cough (Bordet and Gengou), and Sabouraud's medium for ringworm fungi, together with certain recent staining methods, are introduced. Probably the most important addition in this part of the work is the chapter giving methods for the investigation of the changes which are produced in serum by the processes of immunisation and infection. Methods for the estimation of the bactericidal powers of serum, for the carrying-out of hæmolytic tests and other investigations dependent on deviation of complement, are now presented.

There are changes also in the methods of water analysis and in the bacteriology of sewage. In the chapter on B. tuberculosis the methods and results of Much's researches are given, various new media for the isolation of the bacillus are included, and the tuberculin reaction is now treated as part of the general phenomena of supersensitiveness. The recent results obtained by Clegg in the culture of B. lepræ and the frequent occurrence of the Wassermann reaction in leprosy are mentioned. The treatment of the organisms allied to B. typhosus and B. coli has been much altered, and the changes make for greater simplicity and clearness. The changed views on typhoid infection and the importance of carriers are explained, and the paratyphoid and food-poisoning bacilli are treated separately. A general review of the coli-typhoid organisms is finally given, together with a useful tabular statement of the principal reactions of the various members of the group. The diseases due to various spirilla are now collected in one chapter. In the excellent chapter on immunity anaphylaxis is briefly considered, and there is a short section on the serum disease in man. Epidemic poliomyelitis, phlebotomus and typhus fevers occupy appendices.

The form and appearance of the book have not been modified, though the publishers are changed. The printing and paper are quite satisfactory. The illustrations have always been a remarkable feature of the work, and the reproductions seem rather sharper and brighter in this than in the last edition; possibly paper and printing may account for this. A series of admirable drawings by Mr. Richard Muir reproduced in colours have been prefixed to the work. We have no doubt that the new edition will secure the continued and deserved appreciation of all students and teachers of bacteriology.

*The Prevention of Malaria in the Federated Malay States.* By MALCOLM WATSON, M.D. Glasg., D.P.H. Camb., Chief Medical Officer, Estate Hospitals Association, Klang; late Senior District Surgeon, Federated Malay States Medical Service. With Preface by Professor RONALD ROSS, C.B., F.R.S. With 24 illustrations, maps, and charts. Published by the Liverpool School of Tropical Medicine. 1911. Pp. 139. Price 7*s.* 6*d.*

FROM the preface we learn that Dr. Watson was invited by Professor R. Ross to contribute an article to his recently published book on "The Prevention of Malaria," but owing to the amount of material which Dr. Watson had collected it was not found possible to compress it into the space available in Professor Ross's volume. It was therefore decided to issue it as a separate work; and with the assistance of funds subscribed by a number of commercial companies having estates in Malaya, the book has now been published by the Liverpool School of Tropical Medicine. The work is divided into two parts, the first dealing with malaria in the coast towns, and the second with the disease in rural districts. The Federated Malay States possess great natural riches and have an intelligent population; they can also draw upon neighbouring sources of labour. Notwithstanding these advantages progress is greatly hindered by the existence of malaria. The malaria problem here as elsewhere, as our readers are doubtless aware, is largely a financial one. The author has

laboured with great energy and enthusiasm to prevent as far as possible the ravages of this devastating and debilitating malady. He has carried out his campaign for ten years or more, and claims to have proved that the pool-breeding anopheline which transmits malaria on the coast of Malaya and on the flat land can be exterminated by open drainage at a low cost; and that with the extermination of the anopheline malaria has disappeared, the value of the land being greatly increased by the drainage works. Hundreds of square miles of the flat lands have been freed from malaria by simply draining, and by felling the jungle in which anophelines breed. Certain hilly lands intersected by ravines, though opened and drained, remain as malarious as before. In these the transmitting agent is an anopheline (Nyssorhynchus willmori) which, breeding in the streams of the ravines, cannot be driven from them notwithstanding that the streams are kept free from weeds, and which cannot be completely washed out even by the heaviest tropical showers.

Dr. Watson discusses the value of quinine at considerable length, and comes to the conclusion that when it is given regularly in appropriate doses it greatly reduces the sickness and death-rate of those exposed to malaria; but even when persons are taking large doses parasites may be found in their peripheral blood. The value of quinine, moreover, greatly depends on the degree of supervision exercised in its administration. The use of quinine can never, therefore, result in the abolition of malaria, or even make any material reduction in the liability to infection in a malarious locality. As regards special anti-mosquito measures for the stream-breeding anophelines (N. willmori), Dr. Watson recommends that the ravines be thoroughly drained by pipes, from 1½ to 2 feet underground; but he suggests that the most economical and effective method of dealing with malaria on hill estates infested by this particular anopheline will be evolved by the joint work of an entomologist, an engineer, and a medical man. The author is hopeful that with our present knowledge of malaria there will be no difficulty in ultimately eradicating the disease even on the most unhealthy estates. With the disappearance of malaria the solution of the labour problem in Malaya will be attended with comparatively little difficulty. Working on Ross's discovery and on the methods advocated by him, we may, Dr. Watson says, confidently hope to drive out the disease completely from the land. This book is a valuable contribution to the literature of malaria, and ought, in our opinion, to be carefully studied by all who are practically and personally interested in the prevention of the disease.

## LIBRARY TABLE.

*Differential-diagnostische Tabellen der inneren Krankheiten.* (*Differential-diagnostic Tables of Internal Diseases.*) Von J. CEMACH in Wien. Munich: J. F. Lehmann. 21 tables. Price M.3.—A book consisting of tables can obviously present at best a mere skeleton of the subject dealt with. Dr. Cemach disarms criticism by stating in his preface that his tables can only be of value to those who, possessing a good grounding in the general symptomatology and pathology of disease, are desirous of applying their knowledge practically in the diagnosis of the condition of patients. His tables were originally prepared for his own personal use, and are intended for reference in order to facilitate the critical elucidation of the nature of the condition from which a patient is suffering. There are 21 main tables, each one being concerned with diseases of an organ or system, or with a group of fevers. There are in addition a few secondary tables, printed on the back of the others, dealing with certain special conditions, or with symptoms requiring more detailed analysis. In each table the symptoms and physical signs of a number of diseases are classified, and reference is very easy. On the whole, diseases of the blood and of the nervous system lend themselves best to this tabular treatment. Some of the secondary tables are also useful, such as those dealing with the differential diagnosis of asthma, other forms of dyspnœa, ascites, and intestinal obstruction. They suffer, however, from the usual defect of medical tables—viz., they fail to take account of the variability of the manifestations of diseases—in other words, they are too rigid in their analysis. It is obvious that a great deal of labour has been expended in preparing these tables, and if used for the purpose for which the author intended them—i.e., to assist in a rapid review of the clinical characters of a group of diseases with symptoms in common so as to assist in diagnosis—they may be helpful.

*Essays on Duty and Discipline. A Series of Papers on the Training of Children in Relation to Social and National Welfare.* London, New York, Toronto, and Melbourne: Cassell and Company, Limited. 1910.—In this book many papers are reprinted in uniform size from various newspapers and magazines, while addresses are included which have been delivered on various occasions by writers and speakers like well-known persons as the late Professor Friedrich Paulson, Bishop Welldon, Lord Meath, Canon Lyttelton, headmaster of Eton, and Cardinal the Archbishop of Westminster. The dominant note of the book is one of warning. We find in it a lament, unfortunately much needed, over the decay of parental responsibility, the lack of discipline and control of childhood, the loosening of the bonds of legitimate authority, with their inevitable consequences, the prevalent lack of "grit," greed of pleasure, and love of ease. The result of such general deterioration is summarised in the following words of Isabel D. Marris: "History teaches us what is the result, upon a nation, of a love of pleasure and luxury, self-pleasing, and lack of self-control. The laws that have always governed the world are not likely to be altered for the special benefit of the British race. If we, as a nation, follow the same path of indulgence that led to the downfall of Rome and Greece, we English people will just as surely be ruined by our own faults, or conquered by a more disciplined nation, as even the Romans and the Greeks." The pessimism is overdone. None the less, while it would probably be impossible to find any single person, maybe even among the writers themselves, who would agree with all the views expressed in the book, it is certain that many of the papers present material worthy of consideration.

*Transactions of the International Swedenborg Congress held in Connexion with the Celebration of the Swedenborg Society's Centenary in London, July, 1910.* London: The Swedenborg Society. 1910. Pp. 374.—This volume contains the papers read before the Congress, and a brief record of its proceedings. The Congress was attended by representatives from the United Kingdom, the United States of America, Canada, Australia, India, France, Germany, Austria, Switzerland, Spain, Sweden, Norway, Belgium, and Holland. The opening address of the President, Mr. E. J. Broadfield, dealt with the life and work of Swedenborg, touching very briefly on the various departments of theology, philosophy, and science which were illumined by this many-sided man, one of the greatest students of his century. The Congress met in three sections, science, philosophy, and theology. In the section of science addresses were presented by Dr. Axel Andersson, from the Upsala University and the Upsala Royal Scientific Society; by Professor Lönnberg, representative of the Royal Swedish Academy of Sciences; Professor Hj Sjögren (superintendent

of the State Museum for Fossil Plants, Stockholm), representative of the Swedish Board of Trade; Commodore Sundström; Professor S. E. Henschen, professor of clinical medicine, Caroline Institute, Stockholm; Professor O. M. Ramström of Upsala University, representative of the Anatomical Institute of Upsala; Mr. A. H. Stroh, and Dr. Max Neuburger, professor of the history of medicine, Vienna University. The perusal of the papers contributed to this section on Swedenborg as a physiologist, a physicist, and cosmologist will surprise many who do not realise how high Swedenborg stood above his contemporaries and how largely his scientific ideas agree with the results of modern researches. It is fascinating to read of his achievements in respect of the physiology of the brain and the construction and functions of the spinal cord. All this is clearly brought out in the papers by Professor Max Neuburger and Professor O. M. Ramström. These thoughts of cerebral localisation for sensory, motor, and psychical activities appear at first glance as exceedingly modern, but even in Swedenborg's time they were not new, for in the first half of the seventeenth century the philosopher Descartes had already expressed a detailed idea of localisation, which Professor Ramström explains and illustrates in his paper on Swedenborg on the Cerebral Cortex. Dr. David Goyder of Bradford contributes a paper on Swedenborg's Deductions on the Functions of the Ductless Glands, bringing them into line with modern observations; and Dr. A. Rabagliati has papers on the Views of Swedenborg on the Motion of the Brain, that it is synchronous with respiration and not with the action of the heart, and on his remarkable scientific anticipations. This collection of papers will be preserved by the followers and admirers of Emanuel Swedenborg as a complete and interesting history of his achievements, deductions, and inspirations.

*On Acute Intestinal Toxæmia in Infants.* An Experimenta Investigation of the Etiology and Pathology of Epidemic or Summer Diarrhœa. By RALPH VINCENT, M.D. Durh., M.R.C.P.Lond., Senior Physician and Director of the Research Laboratory, the Infants Hospital, London. An Address delivered before the Glasgow Obstetrical and Gynæcological Society on Nov. 23rd, 1910. London: Baillière, Tindall, and Cox. 1911. Pp. 83. Price 3*s.* 6*d.* net.—Dr. Ralph Vincent propounds his views as to the nature of the condition of epidemic or summer diarrhœa, and gives the evidence upon which they are based. He objects to the name by which this condition is usually designated, since he claims that diarrhœa is not an essential symptom, and further that the disease is in no sense an infectious one, and that it cannot be conveyed by contagion. As a result of some experiments on young kittens and of observations upon the disease in children, Dr. Vincent concludes that so-called epidemic or summer diarrhœa, or acute intestinal toxæmia as he prefers to call it, is a disease caused by the absorption of poisons produced by the action of certain putrefactive organisms, which though normally present in the intestinal canal are in normal circumstances unable to produce their effects, since they are inert in an acid medium. The organisms which he discusses in this connexion are bacillus subtilis, bacillus mesentericus bacillus mesentericus vulgatus, and bacillus proteus vulgaris. Dr. Vincent believes that cooking the milk which an infant is fed upon is an important factor in the genesis of the disease. He claims that the organisms producing lactic acid are thereby killed, and thus an important check upon putrefactive processes is thrown out of action. He urges the necessity of securing a pure milk-supply, so that infants may be fed upon raw milk. He recommends the refrigeration of milk at the farms immediately after milking, and its transference to the town in insulated churns. We agree that the collection, transport, and distribution of much of our milk-supply require revision. Other of Dr. Vincent's views are in many ways less easy to support, but if they are heterodox they are also the outcome of a thoughtful study of the problems connected with infant feeding.

## JOURNALS AND MAGAZINES.

*Dublin Journal of Medical Science.*—In the March number Dr. T. Gillman Moorhead gives some notes of a fatal case of myasthenia gravis in which a complete post-mortem examination was obtained. The findings post mortem were thymus persistent, with two well-defined lobes extending down over the pericardium. Microscopically it was normal but contained no eosinophile cells. Thyroid enlarged and more cellular than normal. Kidney slightly congested, and showing parenchymatous changes; both ovaries enlarged and cystic. Other viscera, including red marrow and pituitary body, also spinal cord, medulla, pons, central nuclei, and cortex in the Rolandic region of the brain, normal macroscopically and microscopically. The masseter and pectoralis major muscles appeared normal, but there was some atrophy of the levator palpebræ superioris. No lymphorrhages were found. A consideration of the facts makes the author think that in the future physiologists and pathologists should seek for an explanation of both normal and abnormal metabolic changes more in a study of the inter-relationships of organs and of the effects which the products of one produce upon the functions of another than in the study of the individual organs as isolated structures. Epidemic pneumonia is studied by Dr. Allman J. Powell, who enunciates the view that it is possible that at one time the pneumococcus was an organism of much higher virulence than at the present day, and occasionally it may revert to the former type, producing, when it does so, the epidemic form of pneumonia, "pneumonic fever." Physicians may yet see the day when reversion to the original type may become the rule and pneumonia be classed as a highly infectious fever. Dr. Boyd Barry discusses congenital fistulæ and Dr. James F. Clarke influenza.

*Edinburgh Medical Journal.*—Dr. G. A. Gibson contributes in the March number the introduction to a discussion on arterial pressure at the Glasgow Medico-Chirurgical Society on Nov. 30th, 1910, in which are discussed the definition of terms, the influences at work, the methods of investigation, possible fallacies, arterial pressure in health, arterial pressure in disease, and the treatment of changes in pressure. Dr. Edwin Matthew considers the use of the iodides in high blood pressure and arterio-sclerosis, and concludes that iodides have a marked hypotensive action in high blood pressure without arterio-sclerosis, but none in advanced arterio-sclerosis with high blood pressure. They are vaso-dilators, and to produce a beneficial action in hypertension 10 grains of the potassium salt should be the initial dose, to be increased rapidly if necessary. The organic iodides in the therapeutic doses recommended contain too little iodine to be efficient, and sajodin in corresponding doses should be substituted only in cases in which the iodides are contra-indicated by alimentary disorders. Mr. David M. Greig considers four cases of congenital high scapula, in one of which there was an absence and defective condition of certain ribs, together with a lumbo-sacral hypertrichosis.

ASSOCIATION FOR PROMOTING THE TRAINING AND SUPPLY OF MIDWIVES.—The seventh annual meeting will be held by permission of Lady Brassey at 24, Park-lane, W., to-day (Friday), March 10th, at 3.30 P.M., when the chair will be taken by H.R.H. Princess Christian of Schleswig-Holstein.

FROM
# THE LANCET LABORATORY.

## OMNOPON.

(THE HOFFMANN-LA ROCHE CHEMICAL WORKS, LIMITED, 7 AND 8, IDOL-LANE, LONDON, E.C.)

OMNOPON is the outcome of a suggestion that the total alkaloids of opium might give a combination of effects of special value in certain cases. The suggestion appears to be amply justified judging from the favourable results of its use which have been reported. In our own columns (Feb. 11th, 1911), Mr. C. Louis Leipoldt gave an interesting account of his experience of the value of omnopon in anæsthesia, the omnopon being used as a preliminary to the administration of the general anæsthetic. The innovation is due to Professor H. Sahli, director of the medical clinic in Berne. Omnopon contains the total alkaloids of opium, and quite a number of definite alkaloids have been separated. These, in omnopon, occur as soluble chlorides. The preparation appears as an amorphous yellowish-brown powder dissolving readily in water. For administration it may be obtained in the form of tablets, each 1/10 grain, or of tubes of powder 1/5 grain. In the fluid form omnopon is contained in ampoules, the dose being 1 c.c., which is equal to 1/3 grain of omnopon; 1/5 grain of omnopon is equivalent to 1 grain opium B.P., 15 minims tinctura opii B.P., ½ grain extractum opii B.P., or 15 minims extract. opii liq. B.P. Mr. Leipoldt states that the initial stage of induction of anæsthesia when using omnopon is almost ideal, the patients are absolutely tranquil, and the calming and quieting effect of the drug is much more marked than is the case with scopomorphine. There is no struggling or excitement, the patients breathe deeply and regularly, the pulse is full and slow, while there is an absence of all signs of negativism, and once the case is "under" a very small amount of anæsthetic suffices to keep it in a suitably relaxed condition for the surgeon. On the continent omnopon is known by the name pantopon, the two preparations being identical.

## THERMAL SPRINGS OF BRITISH COLUMBIA.

(ENGLISH AGENCY: D. HATCHER, KINFAUNS, ASHFORD, MIDDLESEX.)

Specimens of waters taken from three springs situated in the Rocky Mountains of British Columbia have been submitted to us for analysis and the results are of interest. The springs are situated in the Sinclair pass in the valley of the Columbia river, East Kootenay. Now that a branch of the Canadian Pacific Railway is opening up this country there is a prospect of the springs being developed for hydrotherapeutic purposes. The samples sent to us were marked A, B, and C, their temperatures at the time they were drawn being respectively 115°, 114°, and 103° F. The mineral constituents present according to our analysis are set out in the following table:—

*Grains per Gallon.*

| | A. | B. | C. |
|---|---|---|---|
| Calcium sulphate | 36·17 | 34·26 | 33·11 |
| Magnesium sulphate | 11·20 | 10·90 | 9·80 |
| Aluminium sulphate | 7·04 | *Nil.* | *Nil.* |
| Sodium chloride | 5·00 | 2·70 | 1·16 |
| Silica | 2·66 | 2·59 | 1·82 |
| Strontium sulphate | 1·70 | 3·36 | 3·40 |
| Calcium carbonate | 1·12 | 6·55 | 5·85 |
| | 64·89 | 60·36 | 55·14 |

Speaking generally, it will be seen that the waters resemble, physically and chemically, the famous springs at Bath. The mineral constituents, at all events, are of the same kind, while the temperatures of the three British Columbia waters agree exactly with those exhibited by three of the thermal waters at Bath. We may conclude, therefore, that these waters from British Columbia and those of Bath will possess therapeutic properties in common. The Bath waters are best known in the treatment of chronic gouty and rheumatic affections and in certain skin disorders. It is interesting, having regard to the facts of analysis, that the British Columbia springs have a considerable local reputation amongst the Indians and settlers chiefly for the cure of rheumatism and skin diseases. The waters show a remarkable degree of organic purity. B and C contained a small but distinct amount of sulphuretted hydrogen, the presence of which, however, is probably due to a partial reduction of the sulphates. We could find no lithia, but strontium was characteristic in all. The waters belong clearly to the class known as thermal earthy calcareous waters. It would be interesting to ascertain whether the water gives off rare gases, as is the case with Bath water, or whether, as is probable, they show radio-active properties, which, of course, can only be determined by careful examination at the source.

## CONCENTRATED GRAPE JUICE.

(CESARE RIGHINI, RIVOLI, ITALY, AND 2, MARLBOROUGH-HILL, ST. JOHN'S WOOD, LONDON, N.W.)

We have not previously examined grape juice which has been so successfully concentrated as this specimen. We understand that the water in the juice has been withdrawn by a freezing process. The concentration may be pushed far enough to produce at length a solid product having the appearance and consistence of crystallised honey. The advantage of this process is that the rarer constituents of the juice are retained, whereas sterilisation by heat, as is well known, removes coagulable bodies. The flavour is excellent, delicately acid, and strongly reminiscent of the luscious grape. On analysis we obtained the following results: moisture, 14·76 per cent.; mineral matter, 0·18 per cent.; protein, 0·17 per cent.; volatile acidity, *nil*; tartaric acid, 0·75 per cent.; grape sugar, 84·14 per cent. In addition to the above we found evidence also of the presence of phosphorus in organic form, whilst, of course, phosphates occurred in the ash, together with decided amounts of iron and manganese. The grape juice, further, is prepared in the form of a jelly which has a very pleasing and attractive flavour, and it is also soothing to the throat. It is obvious that these preparations are particularly well adapted for therapeutic and dietetic use.

## OZET BATHS.

(THE FABRA COMPANY, LIMITED, 24, MINORIES, LONDON, E.C.)

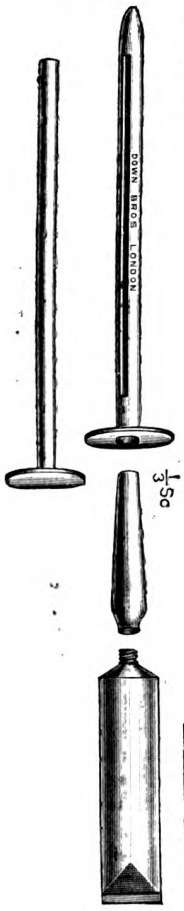
A bath effervescing with oxygen gas sounds attractive, but hitherto it has not been convenient to prepare. The Ozet baths, however, are simple enough and effective. Their composition is based on the fact that a stable peroxide may be made to give up its extra oxygen atom by being brought into contact with a "catalysator." In preparing the oxygen bath, or the oxygen gas-brush as it has been called, all that has to be done is to distribute the peroxide throughout the water in the bath, and then the catalysator is spread in the same manner and the water stirred thoroughly. The patient then enters the bath. The water soon assumes a milky appearance due to the disengagement of minute bubbles of oxygen gas. At the same time myriads of bubbles are formed on and discharged from the patient's skin. As the disengagement of the oxygen proceeds, which is steady and regular, the water assumes a brownish tinge due to the reduction of manganese present in the catalysator. The mixture, however, does not stain nor does it deposit within the time commonly prescribed for immersion. It is stated that one charge will give off 22 litres of oxygen gas. The indications of oxygen baths are somewhat wide, but so far the method has been tried in cardiac disease, rheumatism, gout, skin diseases, and in neurasthenia and in gynæcological practice. The innovation is of interest and merits careful trial.

# New Inventions.

## URETHRAL AND RECTAL OINTMENT APPLICATORS.

I HAVE found the instruments depicted in the accompanying engravings a most efficient means for the application of ointments to the urethra and rectum. They are an improvement on those at present in use, and possess the advantage of simplicity. Each instrument consists of: a metal tube with lateral slits, the lower end being closed with a conically shaped screw; a metal obturator equal in diameter to the internal diameter of the tube; and a metal nozzle with a universal screw at one end which can be screwed on to any ordinary collapsible tube.

FIG. 1.



In using the urethral applicator (Fig. 1) the patient is placed on a couch and the anterior urethra washed out with a pint of antiseptic solution such as hydrogen peroxide 5 per cent., potassium permanganate 1 in 2000, or mercury perchloride 1 in 6000 (a 4-ounce syringe fitted with rubber nozzle should be used). The instrument is sterilised and lubricated with glycerine and is passed without its obturator as far as the bulb (sometimes into the posterior urethra). A nozzle is then attached to a collapsible tube containing the ointment to be used and inserted into the urethral tube, as it lies in the urethra, squeezing the collapsible tube. The tube can be partially filled with the ointment. If the ointment should require liquefaction the nozzle may be heated in the flame of a bunsen burner. Having introduced the ointment the metal obturator is passed gradually. The ointment now exudes through the lateral slits of the urethral tube and the entire instrument is rotated in the urethra two or three times, so as to spread the ointment over the urethral surface. The urethra may be massaged on the surface of the instrument for two or three minutes, starting at the perineal scrotal junction and working up to the fossa navicularis. After removing the instrument the glans penis should be covered with cotton wool, which should be retained until the next urination.

FIG. 2.

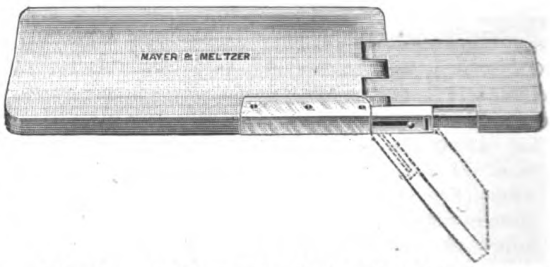
The rectal instrument (Fig. 2) is sterilised and lubricated with glycerine and passed with its obturator, and the obturator is then withdrawn. The rectal tube is filled with the ointment to be used by means of the nozzle attached to a collapsible tube. The obturator is then passed, forcing the ointment into the rectum through the lateral slits of the tube, and the entire instrument is rotated in the rectum so as to spread the ointment over the rectal surface.

Messrs. Down Bros., 21 and 23, St. Thomas's-street, London, S.E., are the makers.

Dublin. ANDREW CHARLES, F.R.C.S. Irel.

## IMPROVED SPLINT FOR COLLES'S FRACTURE.

THE illustration given below represents a splint that I have designed for the treatment of Colles's fracture. The method of using the splint is as follows. The hand piece of the front splint is locked by the brass slide, then the splints are padded and applied in the usual way, care being taken that the back splint does not go beyond the wrist-joint, and that the hinge of the front splint just corresponds with the joint. The bandage which is now applied must not go beyond the wrist-joint, and when this bandage has been fixed a second bandage should be put on extending to the fingers. When it is deemed desirable to move the wrist-joint, all that is necessary is that the second bandage should be removed, then the



brass slide is pushed forward, which will enable the hand-piece to be turned back and the joint manipulated as desired. The advantages claimed for the splint are: 1. It secures movement of the joint without interfering with the fracture. 2. It leaves the fingers free for voluntary movement. 3. It deviates the hand to the ulnar border. 4. By being bevelled it corrects the displacement of the radius forwards. 5. It can be applied to either arm.

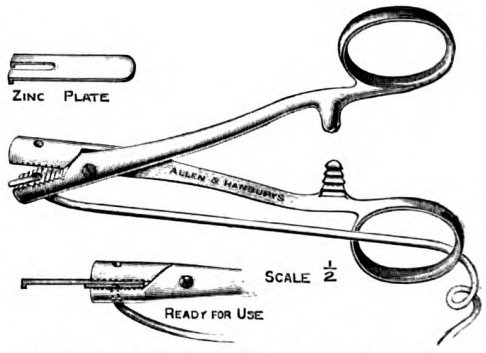
The splints are made in three sizes by Messrs. Mayer and Meltzer, 71, Great Portland-street, London, W.

G. M. DAWKIN, M.R.C.S. Eng., L.R.C.P. Lond.

Pontypridd.

## A NEW CLAMP FOR USE WITH PLATE ELECTRODES.

THIS electrode clamp I have found most useful in the treatment of piles by zinc-mercury ions. For this purpose I take a piece of sheet zinc and cut the electrode to fit the case. Messrs. Allen and Hanburys, of Wigmore-street, London, W., who made the clamp from my pattern, now, however, also supply suitable electrodes for use with the instrument. In the treatment of piles I use a zinc plate about 2 inches long and $\frac{3}{8}$ inch wide, with a slit about $\frac{1}{2}$ inch long and $\frac{1}{8}$ inch wide, cut out at the distal end, thus forming two prongs, the tips of which are bent at right angles into hooks. The object of these hooks is to hold the electrode in the position in which it is first placed, thus ensuring the full reaction taking place all over the area treated, and that of the slit to allow of a view of a portion of the pile under treatment, thus giving the operator his colour index. This zinc electrode I amalgamate with metallic mercury while local anæsthesia is being obtained by means of tampons soaked in cocaine solution. To obtain a direct contact, I bare the end of the



conductor from the positive pole and pass it through the hole drilled in the clamp. The zinc-mercury electrode is then placed in position and the clamp closed, firmly pressing the copper wire against the zinc. The patient now being ready and the piles having been well strained down the electrode is applied to the part to be treated and the operation carried out in the usual manner. I have found this method very useful also in treating ulcers which are in a position difficult to reach with saturated tampons.

*LONDON: SATURDAY, MARCH 11, 1911.*

## State Insurance against Sickness and Invalidity.

THE comprehensive survey of the economic and social conditions of the people of England and Wales which constitutes the report (Majority and Minority documents) of the Royal Commission on the Poor-laws, has revealed the comparative failure in many directions of existing systems of Poor-law medical relief, medical charities, and contract medical practice, and has created a growing demand from the public for the better provision of medical attendance for the wage-earning classes. In the report it is disclosed that a large proportion of the poorer classes do not obtain that prompt and efficient medical attendance which it is to the interest of the community that they should receive; and it is now believed that were the necessary organisation in existence these people, with a little help from the State, could provide themselves with efficient medical service by some scheme of insurance. Since the appearance of the Poor-law report the Government has made known that it has under consideration a scheme of State sickness insurance. There is no certainty as yet that this will include provision for medical attendance, but the belief is general that such will be the case, and there have been statements in the press purporting to give details of the proposals of the Chancellor of the Exchequer for State insurance against sickness and invalidity, based upon the result of a number of private conferences between Mr. LLOYD GEORGE and the members of certain friendly societies. In answering a question recently asked by Mr. BOOTH in the House of Commons, Mr. HOBHOUSE replied that the reports on this matter were issued entirely without the authority and knowledge of the Chancellor of the Exchequer, but he did not deny the accuracy of them. The main features of the scheme are the compulsory insurance of the whole working-class population of the country between 16 and 70 years of age whose incomes are below the income-tax level of £160 a year against sickness and invalidity to a minimum weekly amount of 5*s.*; the acceptance of the risks of all lives good and bad; and the establishment of a Central Administrative Council composed of representatives of the Government, the friendly societies, and the employers of labour to deal with all questions which may arise under the working of the scheme.

In view of the serious extent to which the interests of medical practitioners may be affected by the adoption of schemes of medical attendance under friendly societies' control, and in preparation for the probable eventuality of being consulted by the authorities before any Government scheme is definitely proposed, as well as with the useful purpose of directing the minds of legislators and the public along desirable and satisfactory lines, the British Medical Association, through a committee of its Council, has prepared and submitted to its divisions a report on the "Organisation of Medical Attendance on the Provident or Insurance Principle," and is desirous of obtaining the opinion of the medical profession before adopting a final attitude in supporting or opposing the various plans which will suggest themselves. The report is a valuable and instructive document divided into four sections. Section A deals with the reasons which make it necessary for the medical profession to ensure that the views of medical practitioners shall be ascertained and their interests respected, and contains a paragraph defining the attitude which the profession, in the opinion of the Association, should adopt at the present juncture. It has to be considered, says the report, whether simple resistance to any provident medical organisation undertaken by the community is likely to be of any avail, and whether it might not cause the community to seek other methods of making the desired provision which would be even less satisfactory to the profession. The alternative recommended by the Minority Report of the Poor-law Commission—namely, the employment of a few whole-time or part-time officers, selected by local health authorities to carry out the work of treating the sick poor, which would thus be taken entirely out of the hands of independent private practitioners, is not regarded in their report now made by the committee of the Council of the British Medical Association as desirable either in the interests of the profession or the public, and affords an additional reason for not throwing obstacles in the way of the development of medical services on provident or insurance lines. Section B deals with the general considerations by which the action of the Association must be guided, which is of necessity bound up with previous declarations of its policy. Section C, which forms the largest part of the report, deals with questions affecting the actual organisation of a medical service on an insurance or provident basis. It is a consideration of the constitution of the bodies which may control and carry out the detailed management of the provident service, the part to be taken by the medical profession in such control and management, a definition of the persons for whose requirements the service is to provide, of the benefits to be provided, the sources and amount of contributions to the insurance fund, the principles of selection of medical practitioners employed to attend the insured, and the method and amount of remuneration of those engaged in the work. Section D is a *résumé* of the possible effects of the scheme in the interests of the medical profession and the community. There are indications in the report of the line of action which the committee of the Council of the Association, which prepared the report, considers it desirable that the members should take, but the decision on all questions must be left to the divisions whose opinions have been

asked. This is well, for no action of the Association is likely to be successful that does not carry with it the force of a large body of medical opinion throughout the country, nor is any plan likely to receive a hearing from the Government that does not take into consideration the interests of public bodies, friendly societies, or organisations which at present provide to a limited extent those benefits which it is proposed to extend to the whole necessitous population. The committee emphasises the great importance of not prematurely attempting to enforce a policy on which there is not already general agreement before the course of events from the public standpoint has declared itself, but on certain questions it is regarded as important that the profession should make its views known as soon as practicable. We agree cordially with this attitude.

New methods and new organisations cannot be brought into working without dislocating those in present operation, and without adversely affecting the interests of one or more sections of the community. It is indeed probable that the position of the independent medical practitioner in attendance upon working-class patients will be seriously changed whatever scheme may be ultimately chosen to provide necessitous people with relief at the public expense for their physical needs, but it does not follow that his financial interests will be adversely affected. The total medical assistance provided probably will be much larger than is at present given, and in proportion to the extent of this increase the medical profession should benefit. If to the increase of work demanded be added the certainty of payment for work done, at present an unknown quantity, it will be seen that there are possibilities of advantage to the profession which should be recognised and secured. Whether there will be disadvantages sufficient to annul these will depend largely upon the principles and ideas which underlie any scheme that may be brought about. It is, nevertheless, important if defects exist that they should be pointed out, and an attempt made to prevent the adoption of schemes which are defective and vicious in principle in favour of such schemes as may be defective only in detail and organisation; for whereas the latter may be amended after adoption, the former are not susceptible of such treatment. Very much to the point in this connexion are the remarks of Sir ARTHUR DOWNES in his comment on the Poor-law proposals of the Executive Committee of the County Councils Association, contained in the new edition of Mr. CHARLES BOOTH'S volume on Poor-law Reform which is about to be issued. Whatever proposals may ultimately come to be adopted for medical assistance in the relief of distress, it is very ardently to be hoped that no needless confusion of functions will take place, and that the treatment of the sick will be left as now, a personal matter between practitioner and patient in all cases where it is possible to allow a free choice. There are circumstances where this may not be possible. At the same time it is equally important to point out the danger of placing the whole administrative control of a system of sick insurance with provision for medical attendance in the hands of lay organisations such as the friendly societies and philanthropic bodies.

## The Medical Witness.

THE unsatisfactory position occupied by the scientific witness who is summoned to give evidence in a court of law, whether in civil or in criminal proceedings, is keenly felt by members of the medical profession who are compelled by circumstances, frequently beyond their control, to submit to the ordeal. The matter dealt with may be fitly a subject of controversy, conflicting opinions may reasonably exist, and views may rightly be expressed with regard to it which differ from their own, but their evidence is extracted from them and laid before the tribunal by laymen, the advocates in the case; and the tribunal itself, whether it consist of a judge or magistrate, or of a judge assisted by a jury, has no special qualification to enable it to come to a right decision. In order to remedy a state of affairs which should admit of amelioration, even if perfection may be unattainable, various suggestions have been made. These include one which in effect would involve the abolition of the medical expert witness and the employment of medical advisers appointed by the Crown to examine into and decide upon medical questions, or at any rate to advise the court with regard to them. Among other recent expressions of opinion upon this matter we have before us the report of an address recently delivered before the Academy of Medicine, Ontario, by Mr. Justice W. R. RIDDEL of the High Court of that province.

In discussing "The Medical Man as a Witness" the learned judge refers to the appointing of medical men to make reports to the court, and we are told that in certain criminal cases this is now the practice in Ontario. When there is any reason to suspect the sanity of a criminal two experienced alienists are sent to examine him and report. They are not advocates, and their whole duty is to determine the exact fact. They are at the disposal of the defence as well as of the prosecution. So, too, in cases of poisoning an analysis is made at the instance of the Crown. But even in these cases neither party is bound to accept as conclusive the evidence offered by these experts. Mr. Justice RIDDEL considers it a most dangerous practice to hold any person bound by the opinion of any expert, however able and honest. Medicine is an advancing science, and the official expert may fall behind the younger and non-official authority. A litigant should be at liberty to contest the opinion of an expert in a science which is living and growing, and it must be that other than official experts may be called. This, if we accept Mr. Justice RIDDEL'S view, is fatal to any idea of an official, individual or collective, being appointed as a standing referee upon scientific questions to the exclusion of evidence to be adduced by the parties. His view, moreover, is a perfectly just one. Litigants do not seek the law courts, as a rule, from any wish to do so. We may describe some persons as naturally litigious, or define some claims as "bogus," but we must admit at the same time that the defendant in a civil action goes into court because, rightly or wrongly, someone has sued him, and that the accused in a criminal prosecution is not in the dock by any wish of his own. The Crown in turn prosecutes because of the duty to do so imposed upon it by the constitution, and the plaintiff

who seeks damages does so because, in his view, at any rate in the majority of instances, he has a right to enforce which another denies. Could we without grave injustice, and without risking that confidence in our courts which is a source of pride to us all, say to one of the persons suggested above when his case approaches trial, "You may call any witnesses you choose as to other matters and may testify on your own behalf, but for all medical evidence, or at any rate for medical expert evidence, you must take the man the Crown has selected and abide by his opinion on your case"? This is the position so far as the question of excluding medical evidence adduced by the parties is concerned. The possible introduction of a medical assessor to advise the court where a conflict of medical evidence is expected is another matter. Presumably, if such a state of things were to be brought about the medical assessor and the judge would determine medical questions without the aid of a jury so far as those issues were concerned, and such a system would in many ways be far more satisfactory than the present one.

We have spoken of the assessor as advising the court rather than as deciding the point at issue, because we feel that on the whole it is best that the decision should in form be that of the tribunal charged with the responsibility of the whole trial, and we include in the word "trial" the determination of issues under the Workmen's Compensation Act and other matters to which technically, perhaps, the word trial does not apply. The question of who should decide a question of medical evidence, in the sense of being the person whose judgment is publicly proclaimed upon it, is not quite so easy to answer as those may think who would have a medical expert as sole judge in medical matters. The honoured position occupied by our courts is due in a large degree to a not very easily defined mental attitude of the community known as "public confidence." This may, to some extent, be misplaced, or exaggerated, or due to indifference and acquiescence in existing conditions. So far as our jury system is concerned, no thoughtful person who watches the course of litigation attentively can say that it is perfect, independently of those cases in which scientific evidence has to be considered, and no medical man who gives evidence in a court of law, or who reads reports of trials in which medical issues are decided, can claim that the common or, indeed, the special jury is qualified to express an opinion on medical topics, or that the judge himself, with the advantage of legal training and experience gained as an advocate, is of necessity to be preferred. The object, however, to be aimed at is to replace an unsatisfactory system with a better one, and with one which will be so manifestly and certainly better that the general public will have confidence in it, as well as the medical profession, and those persons who may be qualified by education and mental capacity to discriminate. It is also desirable that the weight of responsibility should be shared, and if litigants and the public should look upon the decision of fact as one arrived at by a trained lawyer and a trained scientist jointly the result would probably be its acceptance, with less tendency to question its correctness than if it were that of the latter only.

We have alluded to the need for the assent of the general public, and we use the term in a wide sense. Persons accused of crimes and litigants who claim under the Workmen's Compensation Act do not constitute the most socially or intellectually important class of those with regard to whom scientific evidence is given in courts of law. They belong, however, to sections of the community whose confidence in the administration of justice must be retained, equally with that of their more influential fellow citizens, if justice is to be administered with dignity and acquiesced in with loyalty. The probable attitude of those occupying judicial positions has also to be considered and of the members of the legal profession who practise before them. From such indications as are available it would appear that the increased employment of the medical assessor to assist the judge in the determination of medical issues would be welcomed by these, but that the exclusion of the medical witness would be condemned, and that the procedure desired is that of the assessor guiding the judge in his decision upon particular points. Reference in this connexion may be made to the instructive discussion which followed an interesting paper upon the Workmen's Compensation Act read by Dr. R. J. COLLIE before the Medico-Legal Society on March 23rd, 1909. Several county court judges spoke and bore testimony to the assistance received by them from medical referees as assessors, and the late Sir JOSEPH WALTON, as chairman of the meeting, added his support to their views.

We may take it that the legal profession would approve of the assistance of medical assessors in suitable cases. But can there be evolved no better system of elucidating medical questions in courts of law which would obtain the full confidence of the medical profession? There can be little doubt that the circumstances in which evidence is now given are not satisfactory to medical witnesses, and are not regarded by the profession in general as leading with certainty to the establishment of the truth. The object of any innovation, however, must be to produce something not only new but better. In this connexion we are of the opinion that the presence of a medical assessor on the bench would be welcomed by medical witnesses while giving evidence, or by those medical witnesses, at any rate, whose opinions on such a topic are worthy of consideration. The medical profession, however, would not, we believe, accept for a moment the introduction of any system which enabled questions relating to the physical conditions of their patients to be determined for purposes of litigation without the patient's medical man being entitled to express and explain his own views upon the subject, by describing the facts which have come under his own observation, and to have expert evidence called to support his conclusions. The present position of uncertainty and dissatisfaction has arisen from the nature of the tribunal before which medical evidence has to be given, and not from any unwillingness of the medical man to enunciate his views and to submit them to the test of cross-examination. He only asks that, if this is to take place, and if his testimony is to be weighed against that of a medical colleague who differs from him, the operation should be performed by machinery capable of fulfilling the task assigned to it; and, if we take into consideration all classes of cases and the contingencies which may arise, he would prefer probably

a tribunal which, in effect, would be composed of a medical man and a judge to the sole arbitrament of an official medical expert. In conclusion, we would submit that extension of the duties of medical referees under the Workmen's Compensation Act, making them necessary assessors to county court judges, would afford an excellent means of testing the value of such assessorship and of introducing it, if it stood the test of practical experience, into other tribunals and into trials of all classes where medical evidence has to be considered. We would, however, point out that, before such a system of assessorship can command the confidence of the medical profession, care must be taken to render the position occupied by the assessor unassailable. He must be a man whose professional qualifications for his post are beyond question, selected on account of his fitness to discharge its duties, a fitness which will not depend only upon the possession of scientific knowledge. In these circumstances the remuneration and dignity of position offered will have to be such as will tempt the best men to leave the profession in which they are distinguishing themselves, just as the emoluments and position of a judgeship in the county courts or in the high court induce a barrister to give up his practice and to accept a judicial appointment.

## Deaf Children.

WE publish to-day the last of the three exceedingly valuable and important articles in which Mr. MACLEOD YEARSLEY, the Medical Inspector of the Deaf Schools of the London County Council, has discussed the education of deaf or of imperfectly hearing children, and has pointed out the methods by which their infirmities may be minimised and their capacities for usefulness and happiness increased in a corresponding ratio. The articles are remarkable for their continual reference of doubtful or disputed questions to the principles of physiology as the only source of safe guidance; and it is not unreasonable to hope that their influence in tending to the establishment of this position may extend beyond the subjects of the particular infirmity with which it is the author's object to deal. We have often pointed out that education, in so far as it is intended to promote the harmonious development of the faculties of the young, is concerned with a strictly physiological process, and can only be intelligently conducted by the light of physiological principles. It is, in fact, or at least it should be, a branch of applied physiology, but in this country at least it has unfortunately fallen much into the hands of persons to whom physiology is a sealed book, and it has consequently been conducted—and too often has this been conspicuous during the last 50 years—in such a manner as to combine the maximum of effort and of expenditure with the minimum of result. Dr. CLEMENT DUKES once called attention to the curious fact that the education of the upper and middle classes of this country is the only pursuit in which persons of no special or ascertained fitness for it, and who have received no special training, are permitted by public opinion to engage; and he might with equal truth have declared that much of the so-called training bestowed upon the teachers of the poor has borne no discoverable relation to the essential character of the duties for which it was supposed to be a preparation. A pupil teacher was "taught" how to "teach" the multiplication table, and it was expected by all concerned that this table would act upon the youthful intelligence like a laminaria tent upon a constricted channel, and that by its own expansion it would mechanically "expand" the intellect of the pupil. It is largely due to American independence of the routine laid down by forefathers, and to American observation and study of the growth of intelligence in the young, that some prospect of a brighter day seems now to be dawning upon us; but that prospect will hardly be fulfilled until there is a definite recognition that the physiologist must teach the teachers. As far, at least, as the recognition of this principle is concerned, we may hope that the work and position of Sir GEORGE NEWMAN at the Education Office, and the increasing influence upon methods of the medical officers of schools, are alike of good augury for the future.

Mr. YEARSLEY'S main contention is that a deaf child comes into the world with a dormant capacity for articulation inherited from millions of generations of ancestors, and ready to spring into activity under the stimulus afforded by the desire to imitate the persons by whom it is surrounded. This stimulus normally appeals, as far as the faculty of speech is concerned, to the nervous centres of the sense of hearing, and to the motor centres which soon form intimate connexions with them; but in the absence or inactivity of the centres of hearing an equivalent, or nearly equivalent, association may be formed with the centres of sight. The sighted but deaf child, instead of listening for sounds and trying to imitate them, watches for facial and lip movements, learns to attach ideas to them and to reproduce them, incidentally in his efforts to do so producing also articulate sounds which hearing persons can understand. The earlier in life the attention of the visual centres is directed towards the facial movements associated with the production of sound the more easy and more complete will become the power of visually discriminating between them, and of reproducing them in such a manner as to produce sounds intelligible to the hearing. It follows that the one essential condition for enabling a deaf child to take its place among hearing and speaking people is that the training of the visual centres in the required direction should be commenced early and continued uninterruptedly. Under Dr. YEARSLEY'S direction important progress in this direction has already been made in the schools for the deaf of the London County Council; but the most striking evidence of the soundness of the principle has so far been derived from American sources. Mr. YEARSLEY refers to the work of the Misses GARRETT at Philadelphia, and the tenth report of the "Home" of these ladies, issued last November, is now before us. The children are admitted at 3 years of age and are transferred to ordinary schools for the hearing at 9 or 10. We have no space for detailed quotation; but the trustees of the home report that their aim is to surround the young deaf children with the same conditions for acquiring articulate speech with which all hearing children are surrounded, the difference being that sight instead of hearing is the medium used. The use of either natural signs, arbitrary signs, or the manual alphabet is strictly prohibited; no one

in the home is, or ever has been, acquainted with either. Appended to the report are many testimonials from teachers and employers, showing that young people educated at the home during early childhood, and passed thence into the ordinary schools for the hearing, have derived the same amount and kind of benefit as hearing children, and are capable of engaging in ordinary industrial occupations, speaking and understanding speech with almost as much readiness as those around them who can hear. From many other American sources similar evidence is obtainable; and it is sufficient to show that, under proper training, the deaf child need neither be suffered to grow up a mute nor in any way be cut off from unrestricted intercourse with his fellow creatures or from participation in their pleasures and pursuits. But all who have had experience of the system concur in the absolute necessity of excluding every description of sign language if complete success is to be obtained; and Mr. YEARSLEY forcibly points out the mischief which has been done by those who have ignorantly endeavoured to combine things which are mutually destructive of one another.

A grave error, which Mr. YEARSLEY'S articles will do much to dispel, is the common belief that deaf children are of inferior intellectual capacity—a belief which could hardly survive a single visit to a well-conducted school for them. The one thing conspicuous about a class of deaf children is their mental alertness and activity. Deprived of hearing, and dependent upon sight for their knowledge of their environment, their bright eyes are fixed upon the teacher or the visitor, their attitudes are erect, their heads well up, and their attention is keenly given to all that they can see around them. So far as our personal experience will carry us, we can also confirm Mr. YEARSLEY'S belief that they are of exceptionally docile and loveable character. It has often been said that the adult deaf take a somewhat roseate view of human nature, and the fact, if fact it be, was explained by FROUDE on the ground that other people reveal only their best sides to them. "It is impossible," he wrote, "to be selfish or worldly down to the level of a hearing trumpet," and it is probable that the deaf child with favourable surroundings is spared the recognition of a good deal of hastiness or petulance on the part both of its elders and of its contemporaries. For those who are less fortunately situated it would be impossible to feel too much compassion; and it is not the least merit of Mr. YEARSLEY'S work that it points to a method by which compassion may be rendered fruitful of good, not only to the deaf themselves, but also to the community. The articles are too valuable and too full of matter to be summarised, and we can only recommend them to the careful study of our readers. We know of no contributions to educational literature which are so manifestly founded upon knowledge, or which so plainly point out the methods by which the majority of a large and hitherto neglected class of the community can be brought into line with the most efficient of their fellow-citizens. Mr. YEARSLEY starts from sound principles, and proceeds to legitimate deductions from them—deductions which he has enjoyed enviable opportunities of seeing justified in practice. As a benefactor to the deaf he will rank with the late Baroness MEYER DE ROTHSCHILD, to whose school, established in 1870 under the management of the late Mr. VAN PRAAGH, and now conducted with great enthusiasm and discrimination by Mr. SIBLEY HAYOCK, he pays a well-deserved and fitting tribute. We have but one criticism of his work, and it is that, when pointing out that oral instruction of the deaf originated in this country, he does injustice to the memory of a great Englishman in attributing it to anyone in the eighteenth century. JOHN WALLIS, Savilian Professor of Geometry at Oxford, and one of the founders of the Royal Society, who, in the words of MACAULAY, "placed the whole system of statics on a new foundation," exhibited to King CHARLES II., and to the Society, in 1663, a "deaf and dumb" youth, named DANIEL WHALLEY, the son of a friend, whom he had taught to speak and to understand speech. WALLIS'S method was applied in a few other cases, and its origin may be traced to his treatise "De Loquela," on the methods of production of articulate sounds. It was therefore no chance discovery, but the ripe fruit of careful and scientific investigation.

# Annotations.

"Ne quid nimis."

## THE DEATH OF PROFESSOR VAN'T HOFF.

BY the death of Professor Van't Hoff at Steglitz, near Berlin, on March 1st, chemical science is bereft of one of its most brilliant exponents. Van't Hoff's great and valuable researches into the realm of stereo-chemistry had their starting-point in the views of Kekulè on structural chemistry. In 1867 the use of models as well as of "graphic" formulæ to represent the linkage of atoms in the molecule came into vogue, when Kekulè pointed out that the models most in favour, consisting of spherical bulbs joined together by rods, were no better than diagrams, since it was impossible to display combination between two atoms by more than one unit of valency, while, further, everything was represented as lying in the same plane. He suggested that by using a sphere to represent the atom of carbon, and four rods to represent its four affinities placed in the directions of four hexahedral axes ending in the faces of a tetrahedron, these difficulties could be got over, and two such models placed together could be used to represent union by one, two, or three units. Van't Hoff developed this idea with most brilliant success. With Van't Hoff, however, must be associated Le Bel, both of whom advanced an identical theory almost simultaneously and independently in 1874. The subject they studied was the arrangement in space of the four atoms or groups united to a tetravalent carbon atom, and they assumed that each of the several atoms or groups with which a carbon atom is united is situated at some point on one of four different lines which are symmetrically arranged in the space surrounding the carbon atom. The existence of isomeric optically active compounds receives a charming explanation on this theory. At all events, it is easy enough to determine, on this assumed arrangement in space of the carbon atoms, whether a compound can exist in only one form or in more forms than one. Out of this grew one of the most beautiful developments of modern chemistry, an explanation of why substances, though being identical in composition—having, that is to say, the same number of atoms in the molecule—yet may exhibit different properties. Van't Hoff worked equally successfully upon the question of solutions. He recognised an analogy existing between

the state of substances in solution and the same in the state of gas, and so the law of Avogadro—that equal volumes of different gases at the same temperature and pressure contain the same number of molecules—was seen to apply to solutions as well as to gases. This development has given considerable impetus to the study of the great physiological processes of the human body. Van't Hoff's record of successful researches is a splendid one, and chemical science is mourning deeply the loss of one of the most distinguished labourers in its field.

## THE MEDICAL BRANCH OF THE NAVY LEAGUE.

IT is no part of our function to engage upon either side in the political controversies of the hour. That, however, does not preclude us from occasionally expressing a word in favour of causes which all healthy-minded citizens must necessarily have at heart. We publish this week a letter from Sir Richard Douglas Powell, in which he draws attention to the existence of a medical branch of the Navy League, and recommends it to the notice of the profession. We are happy to support him. The function of the Navy League is for the most part educational. It endeavours to bring before the citizens of our Motherland and of her dependencies the part which the navy has played in our past history, and our absolute dependence upon it in the present day for our existence as a first-rate power and as a united empire. Endeavours such as these are surely worthy of all the support we can give, and we feel that the medical branch of the Navy League may well be capable of most useful work. The names upon its committee are representative of the larger hospitals, and we sincerely hope that many members of the profession will see their way to joining the branch and widely extending its scope for usefulness.

## PROPER MANAGEMENT OF FOUNDLING CHILDREN.

Dr. Dwight Chapin of New York read before the Section on Pediatrics of the Academy of Medicine at a recent session a paper dealing with the management of foundling children. Dr. Chapin's main argument was that infants should not be kept in large institutions, on account of the fact that when they are massed together they die very quickly. He recommended that foundling infants should be boarded out, and that they should be overlooked in the house in which they have been placed by nurses and medical men. He further proposed that the large institutions and asylums for the care of babies should be abolished and that small collecting stations should be substituted for them. These stations would act merely as clearing houses in which the infant's physical condition might be studied for a day or so. When this had been done and the most suitable food had been decided upon, the infant would be boarded out in the vicinity, where it could be under constant oversight by a physician and a nurse furnished by the station. This plan has been carried into effect by Dr. Chapin on a small scale under the auspices of the Speedwell Society, and a station has been established at Morristown, N.J. In the operation of this work the aim has been to emphasise the following features: 1. Boarding out in a district noted for its healthful conditions. 2. Constant attention to diet and hygiene on the part of a medical man and nurse who are familiar with this class of cases and competent to deal with them. 3. The infants are kept as long as necessary; in fact, until feeding is regulated and digestion and assimilation are improved sufficiently to result in an increase of weight. The work is continued during the entire year. 4. The training in a given neighbourhood of a number of foster-mothers, who by constantly taking such infants into their homes become fairly expert in handling them under conditions totally unlike those offered by the best institutions. The results obtained from the methods practised at the Speedwell Society Station at Morristown have been satisfactory. The death-rate of infants boarded out in this manner has been less by far than in large institutions, and the cost has also been considerably less. The justification of institutional care lies in increase of efficiency by the employment of adequately trained persons at the least possible cost through the concentration of labour and the economic handling of supplies. Its chief objection is the lack of individualism and the blurring of the human personal element by the necessarily machine-like operation of institutional methods. If the plan above suggested should prove on more extended trial to be really less costly than the institutional care of infants, and the process of training numerous professional "mothers" can be extensively followed, it would seem clearly a decided improvement at all points on more usual methods.

## THE WEATHER OF LAST MONTH.

THE general state of the weather of the last month over the British Isles, and to a considerable extent over the continent, underwent a great change after the 13th. During the earlier days there was scarcely any rain, the dry spell which set in about Jan. 12th being continued with only a partial break here and there until the 10th, or for about four weeks. There was, however, in spite of the dryness, little sunshine, and many of the days were marked by mist or a depressing gloom. The temperature, too, was low, and there was sufficient frost to allow a very brief indulgence in skating on some of the shallow waters within a few miles of the metropolis. All parts of the south and south-east of England recorded sharp or severe frost during the first three nights; at Kew Observatory the sheltered thermometer fell as low as 22°, and at Greenwich to 23°. There was also a return of frost for a few nights after the 9th, but the day temperature was then relatively high. With the shift of wind to south and south-west at the beginning of the unsettled period rain fell in some portion of the kingdom every day and on many days over the whole of it, but, as so frequently occurs in this country in winter during unsettled weather, there were several days of brilliant sunshine and many more with quite a fair quantity, while the air, sweeping across the country from the south-west or west, often at the rate of between 20 and 30 miles an hour and sometimes between 35 and 45 miles an hour, had no time to lose its Atlantic mildness, and the temperature of both day and night was much above the ordinary figure for the time of year. The frequent rain was not at all heavy except at times in the West of Scotland, and considered as a whole the aggregate fall was below the normal for February. And the normal February, in spite of the old adage about "fill-dyke," is about the driest month of the 12 in almost all parts of these islands. At Kew Observatory the sheltered thermometer descended below the freezing point on eight nights, and at Greenwich and Hampstead on seven, while on ten afternoons the temperature was as high as 50° or above at Kew and Greenwich and on nine at Hampstead. Owing to the occasional cloudless or nearly cloudless skies after the 11th the sunshine was in excess of the average in some parts of of the kingdom, the excess being especially large in London. At Westminster the total number of hours was 54, or 20 more than the average; at Greenwich the number was 64 hours, or seven more than the average; at Kew 67 hours, also seven more than the average; while at Hampstead, where the observations do not yet afford a trustworthy average, there were 70 hours. The latter

portion of the month was very windy, and the air inhaled in London and the large cities of the Midlands and the North was, only a few hours previously, rushing over the Atlantic or the Bay of Biscay. In the South of Europe the earlier days of the month were cold and fine. Sharp frost was recorded again and again throughout Italy, and on the Riviera the sheltered thermometer fell as low as 27° on the 1st. Italy was, however, much colder than the Riviera, and on the 9th Naples experienced a lower temperature than has London during the whole winter, the thermometer falling to 19°. Further south, at Brindisi, the temperature on the same occasion was as low as 28°, while a furious gale from the north brought a prolonged fall of snow. Palermo and Malta only shared in a very moderate degree in the cold weather, the thermometer rising to between 50° and 55° every day and sometimes going higher, while the weather was generally fine. The last fortnight was very different both in Italy and on the Riviera: the cold wind current died away, and the general state of the sky being fair the sun could assert its growing power, and instead of being frosty the nights became relatively mild, while some of the afternoons were excellent imitations of spring. Temperatures of 60° and above in the shade became almost common, while towards the end of the month the genial warmth of 65° was registered on at least one afternoon, but at Malta and Palermo the approach of spring was even more marked, the thermometer rising to a little above 70°, and a similar figure was recorded on the coast of Algeria. Night frosts were very common at Biarritz until the month was well advanced, but a really cold day was seldom experienced, and although there was less sunshine than on the Riviera the weather was mostly very pleasant. Switzerland and the surrounding part of the continent enjoyed excellent weather for the winter sports, experiencing almost arctic cold until after the middle of the month. The sheltered thermometer dropped to nearly zero Fahrenheit even at ordinary levels, while among the mountains the frost was much more intense. The day-time, which was often very bright, had relatively little effect on the temperature, and for a long period there was nothing resembling a thaw. Subsequently there was a decided increase of temperature, and later in the month rain was more frequent than snow.

## THE DURATION OF INFECTIVITY OF ENTERIC FEVER.

IT is now an accepted fact that in convalescence from certain infectious diseases patients may harbour in their bodies the pathogenic organisms of these diseases, and in that way be a source of danger to other people. In diphtheria the bacillus may be found in the throat for some time after all symptoms of the disease have disappeared. In pulmonary tuberculosis, also, tubercle bacilli may be found in the sputum when all clinical evidence tends to prove that the disease has been arrested. Typhoid carriers are now well known to exist, and it is an important point to ascertain if possible how long patients convalescent from enteric fever may pass typhoid bacilli with their stools and urine. In another column we publish an article by Dr. Alfred Harris dealing with this subject. He states that in order to estimate the length of time during which bacilli may be excreted a routine examination of the stools has been carried out during the last few months in the case of all enteric fever patients treated in the isolation hospital at Southampton. There is considerable difficulty in carrying out such an investigation owing to the multitudes of bacilli which flourish in the intestine, and it is not easy to devise a method by which the colonies of the typhoid bacillus can with certainty be isolated. Dr. Harris explains the methods which have been adopted. The researches of Conradi and Drigalski are well known, and these observers have done much to facilitate the necessary separation of the colonies. Dr. Harris found, however, McConkey's neutral-red bile-salt agar to be the most reliable culture medium. The results of his investigations are shown in tables, and some interesting points arise. One is the great variability which exists in the period when a negative result was obtained. In some instances between 40 and 50 days elapsed before the bacilli disappeared. In one instance a positive result was obtained 78 days after the temperature had become normal. Another point is that the persistence of infection bears no relation to physical signs. For instance, the case already mentioned, in which the bacilli persisted in the stools 78 days, had been a mild one with but little diarrhœa. The whole subject of carriers in infective diseases is a most important one from the point of view of prophylaxis. At present our knowledge is scanty concerning the length of time that the bacilli remain active in various conditions, but with investigations being carried out on the lines which Dr. Harris has adopted the exact danger of infection from this source should become known.

## THE CHILDREN OF ASCLEPIUS AND THE GOOSE.

IN a recent number of the *Archæological Journal of Athens* M. Svoronos publishes a reproduction of a charming ancient Greek statuette representing a boy and a goose, which has recently been added to the city's museum. There are numerous examples from Greek antiquity of these groups; frequently the child is strangling the bird, and hitherto they have been considered merely as a curious artistic conceit. But M. Svoronos argues that really they have a religious and mythological significance. The goose was a sacred bird of Asclepius, and all these goose and child groups, whose original location can be ascertained, come from sanctuaries of Asclepius. The newly-found poems of Herondas describe a similar group in the deity's temple at Cos. M. Svoronos maintains that in these works the boy represents Ianiscos, youngest son of Asclepius, when he is strangling the goose, the bird being a symbol of the pestilence-producing pools and marshes, and so the statues typify the healing of fevers by Asclepius and his family. Other of the groups depict Asclepius himself as an infant, or one of his daughters, with a goose. The Spinario in the Capitol at Rome is, however, he thinks Podalirius, another son of Asclepius. Pliny mentions a famous piece of sculpture by Boethius of a boy strangling a goose, a work which must be later than the one Herondas describes. Probably many of the statuettes are copies of one or other of these works. M. Svoronos has also succeeded in definitely ascribing the figures in the famous Asclepian relief found in 1885 and now in the Athens Museum. The seven personages are: Asclepius, Machaon, Podalirius, Epione, Panacea, Iaso, and two suppliants, the three dogs representing those kept at the shrine of the god.

## SPOROTRICHOSIS.

THE first account of a disease due to a sporothrix was given by Schenck in 1898, who had found it in a patient with multiple subcutaneous abscesses along the course of the lymphatics of the arm. Since then many other cases have been described, chiefly in France and America, but so far as we are aware no certain cases of the disease have hitherto been described in England. In the present issue of THE LANCET Dr. E. von Ofenheim has reported a case which was under his care; the patient suffered from a number of enlarged lymphatic glands in the neck and a swelling over the tibia. The cultures taken from the fluid withdrawn by an aspirator from the swelling

on the tibia grew an organism somewhat like a yeast, but differing from it in several points, and Dr. Ofenheim is inclined to believe that the organism is a sporothrix. So far as can be judged from the data supplied it appears to us that his diagnosis is probably correct. Dr. Ofenheim in his report does not mention whether potassium iodide had been administered to his patient. This drug has a remarkably active effect on sporotrichosis, and it might be well to see whether it has any effect on the case recorded here. It is difficult in these cases to make a diagnosis merely from an examination of the pus withdrawn, but by the cultures it should be possible. Until comparatively recently the fact that a lesion was removed under the influence of potassium iodide was considered to be sufficient to make certain a diagnosis of syphilis, but it is now fully recognised that several other conditions, such as actinomycosis, blastomycosis, and sporotrichosis, also respond readily to this drug.

## PLAGUE AND RODENTS IN CALIFORNIA.

WHILE we are considering how to deal, if in the unfortunate event it should become necessary, with the dissemination of plague in East Anglia, the very same problem is facing our cousins in California, where the ground squirrels have long been known to be seriously infected. Details are given in an interesting paper in the *Military Surgeon* for January, from the pen of Passed Assistant Surgeon W. C. Rucker of the United States Public Health and Marine Hospital Service, from whose account we quote. Plague came to San Francisco in 1900, brought by sugar-ships from Hawaii; they unload in Costa County, 20 miles north of San Francisco, where it was noted in 1901 that a deadly epidemic raged among the ground squirrels (Citellus Beecheyi), "the most prevalent small mammals in that county." No plague infection was found among them at that time. The epidemic almost exterminated them, and they did not again become numerous until 1908. Plague lasted four years in San Francisco, killing 225 people. After 1904 only scattered cases occurred, and these, it was noted, in people who had no chance of infection by rats, but who had shot, or trapped, or eaten ground squirrels. In 1907 plague again broke out, the squirrels were suspected, and in 1908 a large number were examined and four were found to be plague-infected. In 1909 the Public Health and Marine Hospital Service, "which had charge of the plague situation" in California, took the matter in hand, and found infected squirrels in almost all parts of Costa County, also beyond it. Ground squirrels are infected over an area of miles one-seventh of the State of California. They are not themselves very widely distributed, but the wood rat (Neotoma fuscipes), which is found nearly all over the United States, has also been known to be plague-infected, which makes the problem more troublesome. The ground squirrel's flea (Ceratophyllus acutus) transmits plague to rats, and the rat's flea (C. fasciatus) will infect the ground squirrel, and those who catch or cook ground squirrels risk contracting plague from their fleas. The Public Health and Marine Hospital Service are studying the life-history and distribution of the squirrels most carefully, with a view to their eradication by poisons, by encouragement of their natural enemies, and by the use of noxious and explosive gases. A ground squirrel is supposed to eat food to the value of 4*s.* yearly, and this financial loss and the desire to avoid plague are uniting the State and county authorities, the farmers' clubs, and the individual landholders in a combined attack upon the squirrels. The United States has a favourable position for this contest, supported as it is by the permanent Federal organisation and the well-trained officers of the Public Health and Marine Hospital Service, whose efforts will, we trust, achieve success. Passed Assistant Surgeon Rucker's paper should be widely read—perhaps the Society for the Destruction of Vermin might ask his permission to republish it here.

## THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND THE UNIVERSITY OF LONDON.

AT a recent Comitia of the Royal College of Physicians of London the report of a committee of the College appointed to consider the report dated Feb. 15th, 1910, of the delegates appointed by the Royal Colleges in 1908, was received. The report of Feb. 15th of the joint delegates had reference to the establishment of a system of conjoint examination between the Royal Colleges and the University of London in accordance with Statute 123 of the University.[1] The report suggested that the Royal Colleges should jointly give evidence before the Royal Commission, now sitting to inquire into the working of the reconstructed University, on the present disabilities of the London student; and on the desirability of an association between the Royal Colleges and the University in a scheme for granting, on terms, the medical degrees of the University with the diplomas of the Colleges to the students who have completed at least four years at a London medical school. A scheme as a basis of such negotiation was set out in the report, which concluded with general expressions as to the desirability of the Royal Colleges preserving their autonomy in every other respect. This report was, on March 14th, 1910, referred to a large committee of the College for report to a future meeting of the College on the whole subject, and the large committee has now advised the College that it is, in its opinion, inadvisable that the College should take any steps to promote the scheme of conjoint examinations outlined in the report of the joint delegates. The report of the large committee was adopted, whereby, in our opinion, an excellent opportunity was lost for improving the professional status of the London student.

## MEDICAL OFFICERS' FEES IN INDIA.

THE following revised rules have been issued by the Government of India, applicable to British India and native States, regarding the receipt by medical officers of the Government of fees (including honoraria or presents) which may be offered for services rendered or for professional services in certain cases:—

1. Whenever attendance, whether for an ordinary visit, a consultation, a confinement, or a surgical operation on a ruling chief or his family or dependents, or on an Indian of position who holds a hereditary title conferred or recognised by the Government of a rank not below that of Raja or Nawab, or his family or dependents, involves the absence of a medical officer from his station, he shall be permitted to demand or receive such fees as may be arranged between himself and the person employing him, provided that he does not, without the special permission of the local government, obtained as provided below, demand or receive, in addition to his travelling expenses, a higher fee than Rs.500 (£33 6*s.* 8*d.*) a day for the first three days, and Rs.250 (£16 13*s.* 4*d.*) a day thereafter; the full daily fee being given for every complete period of 24 hours' absence with a proportionate fee for periods of less than 24 hours.

2. For similar attendance not involving absence from his headquarters a medical officer may demand or receive fees in accordance with the scale which he has fixed for his patients generally, and in the case of operations and confinements he may accept fees equal in amount to those current in similar circumstances in the profession in the United Kingdom.

3. Before accepting or demanding for a ruling chief or Indians of position, as referred to in Rule 1, a fee in excess of the rates laid down in the Rules 1 and 2 above, a medical officer must report the case confidentially to the local administrative medical officer, who will obtain unofficially and communicate to him the orders of the local government. When taking the orders of Government administrative medical officers will be careful not to disclose any of the medical particulars of the case.

4. Local governments and administrations shall have full power to dispose of all cases so reported to them, but shall be at liberty to consult the Director-General, Indian Medical Service, or to refer any particular case for the orders of the Government of India.

Granted the necessity for any regulations at all in these

[1] THE LANCET, March 19th, 1910, p. 814.

matters, the Government of India appears to have been advised wisely. Ridiculous restrictions to legitimate practice have been withdrawn, while adherence is assured to a proper scale of charges in the matters of operations and confinements.

## CRIMINAL STATISTICS AND PENAL REFORM.

THE monthly record of the Penal Reform League for March, which has been forwarded to us by the honorary secretary of the league, Captain Arthur J. St. John, takes occasion, in referring to the recently published Blue Book on Criminal Statistics,[1] to discuss the cause of the alleged relaxation in public sentiment with regard to crime, and suggests that one reason for this feeling, so far as it exists, may be found in the somewhat meagre results hitherto attained by our penal methods. In this connexion the high rate of recidivism is instanced as a proof that punishment does not seem to be either deterrent or reformative, and it is asked whether failure may not be due, as has been recently maintained by Mr. Thomas Holmes, secretary of the Howard Association, to the fact that a considerable proportion of recidivists are mentally defective and are quite unamenable to ordinary penal treatment. It is very satisfactory to find that intelligent lay opinion is awakening to this serious failing in our machinery for dealing with the criminal; and it is still more gratifying to observe that the consideration of this point is leading to the further inference that no penal methods can be satisfactory which are not based on an adequate knowledge of the individuality of the criminal. In impressing this view on the public the Penal Reform League should do extremely useful work, and as the league apparently includes in its membership several persons of distinction in the political world, it may perhaps be able to exercise some propagandist influence on our legislators, who, if we may judge from various incidents in the last few years, are in no hurry to recognise the rôle of science in the treatment of the criminal.

## A NEW SIGN OF PLEURITIC EFFUSION.

IN the *Progrès Médical* M. Félix Ramond has called attention to a new sign of pleuritic effusion which he terms "the sign of the spinal muscles." He has found that on the affected side the erector spinæ is in a state of reflex permanent contraction. On inspection of the lumbar region the muscular mass appears more prominent and broader than on the sound side. On palpation the muscles give a sensation of hardness and resistance which may be compared to that of a cord of indiarubber slightly stretched, very different from the softer sensation given by the muscles on the sound side. If the upper attachments of the longissimus at the level of the sixth and seventh dorsal vertebræ be struck with a percussion hammer at a distance of two or three finger-breadths from the middle line the sensation given by palpation of the lumbar region is still more characteristic; the muscles vibrate under the finger and sometimes the contraction is so strong as to be visible. However, this last phenomenon is not so characteristic as the others, for it may be found in patients with exaggerated muscular irritability, particularly cachectic, alcoholic, and neurasthenic persons. These three phenomena, which are obtained by inspection, palpation, and percussion respectively, may all be present together or only the enlargement of the muscular mass may be evident. If the other phenomena seem absent or ill-marked they may be evoked by telling the patient to bend slightly alternately to one side and the other. Normally the spinal muscles on the side to which the body is bent become completely relaxed and soft, while those on the opposite side become tense and hard. In pleuritic effusion, when the body is bent towards the affected side, the muscles on that side do not completely lose their tone, and when the body is bent to the opposite side their hardness increases. In certain cases of pleuritic effusion M. Ramond has found to his surprise that the sign was present in slight degree on the sound side. With this there was marked dulness in Grocco's triangle. In three out of seven such cases he found on paracentesis a little fluid in the pleura which was supposed to be normal. He does not claim that this explains all the cases in which Grocco's sign is present, but he concludes that when the sign of the spinal muscles is present in slight degree on the side supposed to be sound a little effusion on this side may be suspected. The sign persists for three or four weeks after recovery from the pleurisy and may therefore be used for retrospective diagnosis. In some cases it persisted much longer—six months, nine months, and in one case three years. Its persistence is of bad significance and indicates that the inflammatory process has outlasted the effusion, and that recovery is only apparent. M. Ramond has found the sign constant in "primary" pleurisy and present in 94 per cent. of cases of pleurisy complicating old pulmonary tuberculosis. It was present in 3 cases of pleurisy in Bright's disease, but was absent in 3 out of 8 cases of hydrothorax of cardiac origin. It was present in 4 out of 7 cases of empyema. The following case is of particular interest. A youth, aged 19 years, had pain in the side and effusion three weeks after a severe contusion of the thorax. The sign of the spinal muscles was present. Puncture yielded slightly turbid fluid. Subsequently the effusion became purulent and the sign disappeared. It seems, therefore, that the sign has a tendency to disappear as the effusion becomes purulent. The sign seems to be peculiar to pleurisy with effusion and absent in other thoracic affections, though observations on this point are not yet sufficiently numerous. Thus, it was absent in 3 cases of pneumothorax without effusion and in 3 out of 5 cases of pneumonia. In the other 2 cases of pneumonia there was probably some inflammation of the pleura. The value of this new sign is increased by the fact that, excepting dulness, all the signs of pleuritic effusion are more or less inconstant.

## PIONEER MEDICAL WORK IN AUSTRALIA.

IN an address to the members of the Women's Institute last week Miss Amy Hughes, general superintendent of the Queen Victoria's Jubilee Institute for Nurses, gave an interesting sketch of the difficulties of getting and of rendering medical assistance in the outlying townships and scattered hamlets of Australia. Often one farm may be 20 or 30 miles from the next habitation and 130 miles from the railway. Ordinary practice under such conditions is impossible, and Miss Hughes explained that one of the first acts of a medical man after settling in a new township is to open a small hospital. News of this soon spreads to the outlying farms and hamlets, and patients come in either for accidents or illness, glad to avail themselves of the only possible means of receiving medical treatment. Of course symptoms are often aggravated and complications set up by the long journeys over rough roads; but these miniature hospitals are fitted in a remarkably up-to-date manner with modern appliances, while surgery, owing to the prevalence of accidents in the mining and smelting districts, is extensively practised. When the demand exceeds the supply of the four or five beds with which the hospitals commence the State comes to the rescue, and for every £1 raised by the inhabitants of the township

[1] THE LANCET, Feb. 25th, 1911, p. 519.

gives another £1 for expenses of building and maintenance. The medical man can be communicated with by means of the telephone, which is carried to most of the hamlets and settlements, and further to facilitate matters the Government has placed receivers on the line at various points; into these messages may be placed from houses on or near the line, and are collected by the "boundary rider" on his rounds and taken to the nearest call-office. To certain districts a train goes once a fortnight, and even then to reach the settlements beyond the journey has to be finished on camel-back, a circumstance which will surprise many of our readers.

## CAMPING OUT IN TUNISIA.

A CIRCULAR that has reached us from Tunis opens up a pleasant vista of a new form of "rest cure"—viz., camping out in the desert. The season is stated to last from October to May, but personal experience leads us to infer that mid-winter is a by no means agreeable season even in the desert, seeing that though the sun be warm the northern blasts are piercing and the nights are extremely cold. Assuming favourable climatic conditions, we can well imagine that a properly organised excursion would afford a delightful and restful holiday for persons whose vitality has been sapped by social or professional excesses. There remains the question of congenial companions, a risk which it is almost necessary to incur on account of the greatly increased expense when only one or two persons are catered for. The tariff, which for more than three persons is fixed at 40 francs per head per day (rather over 30*s.*), is 80 francs for a single person, 70 francs for each when there are two, and 65 francs when there are three—not exorbitant sums in view of the multiple preparations that have to be made. Tunisia is out of the beaten track, but is perfectly safe for travellers within prescribed limits, and it affords a wide range of objects of interest. There are venerable ruins in abundance, remarkable hot springs, and, above all, the "wide quietness" of the illimitable desert with its ever strange, wandering inhabitants, and its numerous oases. The dry, invigorating air, the marvellous contrasts of sky and sun, the brilliant nights, the trackless sands, the thousand and one incidents of a nomad life, freed as far as may be from the disadvantages inherent thereto, and life absolutely in the open air where the silence is at times almost tangible—these are features which, in conjunction with the total absence of disturbing influences from work-bound climes, constitute a rest-cure in the largest and best sense of the term. From inquiries we have made there is every reason to believe that the scheme is perfectly practicable, and those of our readers to whom a prolonged holiday under these conditions appeals can place themselves in communication with Messrs. Pernull and Myddleton, 39, Avenue Jules Ferry, Tunis.

THE King has approved of the nomination of Mr. J. Pringle, M.B. Aberd., C.M.G., and Mr. J. E. Ker, L.R.C.P. Lond., M.R.C.S. Eng., as members of the Legislative Council of the Island of Jamaica.

IN our list of New Year's honours we omitted to note that Major R. J. Blackham, R.A.M.C., sanitary officer of the First Division, Indian Army, received the Kaiser-i-Hind medal of the Second Class.

COLONIAL MEDICAL SERVICE.—*West African Medical Staff:* Mr. H. C. Jeffreys, medical officer, Sierra Leone, has been transferred to Northern Nigeria, and Dr. C. S. Thompson has been selected for appointment to the staff and assigned to Southern Nigeria.—*Other Colonies and Protectorates:* Dr. E. N. Darwent, resident surgeon of the Colonial Hospital, Trinidad, has been appointed district medical officer, Arima district, Trinidad.

# A FORGOTTEN PROPHECY OF THE MICROBIC THEORY OF INFECTIOUS DISEASE.

BY CHARLES SINGER, M.A. OXON., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO THE DREADNOUGHT SEAMEN'S HOSPITAL; REGISTRAR TO THE RESEARCH INSTITUTE, CANCER HOSPITAL.

IN 1877 Louis Pasteur, by a series of brilliant generalisations based on innumerable experiments, was able to state that—

> Anthrax is the disease of the bacteridium as trichinosis is the disease of the trichina, as itch is the disease of its special acarus, with this circumstance, however, that in anthrax the parasite can only be seen through a microscope and very much enlarged.

Although the microbic theory thus set forth by the great investigator was built on the knowledge acquired by himself and his contemporaries, it yet had its roots in a more remote generation. Without going back as far as Fracastor,[1] who already in the fifteenth century had some idea of "the seeds of disease," there was in the early part of the eighteenth century a group of men who made more or less confused efforts to associate the new discoveries of microscopic life with the obscure and mysterious phenomena of infection and with the occurrence of epidemics. The clearness and definiteness of the views of one of these writers is, however, very remarkable, and it is strange that a man who foresaw with such distinctness some of the most important modern biological discoveries should have been so completely forgotten.

In the year 1720 there saw the light in London a small volume bearing the title, "A new Theory of Consumptions: more especially of a *Phthisis*, or *Consumption* of the *Lungs*, wherein ..... *Enquiry is made* concerning the Prime, Essential and hitherto accounted Inexplicable *Cause* of that Disease, so very *Endemick* to this Nation ....." by one Benjamin Marten, M.D. In the course of this book Marten sets forth the various hypotheses of the ancients as to the nature of infection, together with the views that were current in his day. Dismissing all these as inadequate, he gives his own conclusions, which the reader will recognise as being neither more nor less than the germ theory of disease as we have it to-day, clearly conceived and applied, not only to consumption, but also, it is interesting to note, to such conditions as syphilis, rheumatism, and leprosy, as well as to small-pox, measles, plague, and the common cold.

In what follows Marten's quaint language and spelling have been preserved, and beyond the addition of headings for the guidance of the modern reader and a few small changes in order the matter is exactly as he wrote it.

### *A General Statement of the Theory.*

The *Original* and *Essential Cause* then, which some content themselves to call a vicious Disposition of the Juices, others a salt Acrimony, others a strange Ferment, others a malignant Humour (all which seem to me dark and unintelligible) may possibly be some certain Species of *Animalcula* or wonderfully minute living Creatures, that, by their peculiar Shape, or disagreeable Parts, are inimical to our Nature; but, however, capable of subsisting in our Juices and Vessels, and which being drove to the Lungs by the Circulation of the Blood, or else generated there from their proper *Ova* or Eggs, with which the Juices may abound, or which possibly being carried about by the Air, may be immediately convey'd to the Lungs by that we draw in, and being there deposited as in a proper *Nidus* or Nest, and being produced into Life, coming to Perfection, or increasing in Bigness, may by their spontaneous Motion, and injurious Parts, stimulating and perhaps wounding or gnawing the tender Vessels of the Lungs, cause all the Disorders that have been mentioned, viz., a more than ordinary Afflux of Humours, upon the Part, Obstruction, Inflammation, Exulceration, and all other the *Phenomena* and deplorable Symptoms of this Disease.

### *The Possibility of Intra-uterine Infection.*

Nay it will not be difficult to suppose it possible, that as the Fluids of our Parents might abound with many Species of *Animalcula*, so the *Ova* or Eggs of them may have been communicated to us, or convey'd into our Fluids with the Nourishment we receiv'd through the *Umbilical* Vessels, even whilst we were in the Womb, and may possibly lie latent in us for a longer or shorter Term of Years, till either our vessels are become of a fit largeness to afford 'em a proper *Nidus* or nest, or our Juices of such a Property as is fit to nourish and produce them into Life.

And thus we may possibly account for several Diseases to which we are liable Hereditarily. This may be one way perhaps by which the Small Pox is convey'd from Parents to Children, from Generation to Generation; which Disease I am not only apt to think is primarily caused by inimicable *Animalcula*, or wonderful minute Animals in our Fluids, but also verily believe, it may be certainly prevented, especially

[1] See Fracastorius, by W. Osler, Proceedings of the Charaka Club, vol. ii., 1904.

in Adults or grown Persons, by destroying the very Essence of the Distemper. .....

### *Specific Diseases due to Specific Organisms: Plague, Small-pox, Rheumatism, Phthisis.*

And as it is reasonable to suppose that there are various Species of *Animalcula*, so of Course they are of various Magnitudes, of different Shapes, and have peculiar Parts ..... so various Diseases, more or less sudden and pernicious may be caused (by them).

For how can we better account for the regular types, the Small Pox, Malignant, and all other Continual and Intermitting Fevers, as well as many other Distempers, keep, and the peculiar Attributes and *Crises*, *etc.*, they have, than by concluding they are severally caused by innumerable *Animalcula*, or exceeding minute Animals that variously offend us according as their Species are different, and as their peculiar Shape and Parts are more or less injurious to our Fluids and Solids. .....

By what has been said, I think ..... there is possibly no Ulcer or ulcerated Matter, but what is stock'd with *Animalcula*, and as these are of different Species and more or less capable of injuring the Parts in which they are bred or lodged, so those Ulcerations may be more or less stubborn or Inveterate.

### *Epidemic Disease in General in both Human Beings and Animals considered in the Light of the Theory.*

And as we may reasonably imagine that each Species of such *Animalcula* or exceeding minute Animals, keep together in vast Numbers, as we find the Species of such Living Creatures as are big enough to be seen by the bare Eye, delight to do, as Shoals of small Fish, and swarms of flying Insects, so we may easily conceive, if this Theory be admitted, how it happens that sometimes a pernicious Disease becomes Epidemick or almost general of a sudden, without respect to either Age or Sex.

How Distempers happen to rage in one Year, or Season of the Year, or in one Country or Part of a Country, more than in another, as the Plague, Pestilential and other Fevers, Small Pox, Measles, and several other Diseases, and how they are spread by Degrees, and are communicated from one Person, and from one Country to another, may by this Theory perhaps be more easily explain'd than by any other.

What way can we better account for Coughs, that become at some particular Times *Epidemical* or almost Universal, and that indifferently as to the Season of the Year, than by this Doctrine? As also for several other Distempers that we find at some Times not only to afflict Men but Destroy Beasts.

It is allow'd by all the Learned, that most Nations are infested with Distempers, that in an especial Manner are more peculiar to them, than to others, yet it is certain that some such Diseases may be, and often are transplanted into Distant Countries, and sometimes flourish as much in a new Climate as in that from whence they came; thus it is generally supposed that *Europe* is indebted to *America* for the Venereal Disease, as I am inform'd that is to *Europe* for the Small Pox, of which we made them a present, in return for the *Grand One* they made us.

If it be once allow'd that the Plague, Pestilential and other *Epidemick* Diseases are caused, and carried on by very minute volatile Insects, we may then easily conceive how they are conveyed to and from Distant Countries or Climates, viz.: by such Volatile *Animalcula* or their *Ova* or Eggs being deposited in the bodies or Cloaths or Goods of Travellers, etc,

### *Leprosy.*

The Plague of Leprosy mention'd in *Holy Writ*, to effect not only the *Jews* but their cloathes, and the very walls of their Houses, (known by greenish or reddish Streaks eat into the Walls, &c.) as described in the 14th chapter of *Leviticus*, was perhaps propagated by means of imperceptible volatile animals.

### *Scabies and Syphilis.*

We find some diseases are apparently communicated from one person to another by Contact or Touching only, of which the Itch and the Venereal Distemper are eminent Instances; that the Essential cause of the former disease, is a vast number of Minute Animals, that by their spontaneous Motion and injurious Parts make Furrows under the *Epidermis* or Scarf Skin, may be demonstrated by viewing through a good Microscope a small Portion of the Humour contained in the little Bladders that arise in that Distemper between the Fingers, &c., in which may be perceived abundance of ill shap'd Creatures, that by nestling under the *Cuticula* or Scarf-skin, stimulate the Nervous Fibres and Cause the troublesome sensation of itching *etc.*

Some of these minute Insects contain'd in a very small Part of that Humour, fixing upon a sound Person's Skin, either by shaking Hands with an Itchy Person, or wiping with the same Towel, or drawing on one of his Gloves &c., will soon insinuate into the Pores, and there increase and multiply and quickly act the same Part in that Person, as in the other, from whence the Disease was received, as innumerable Examples convince us.

And I conceive the latter, or Venereal Disease to be communicated after the same Manner; only as we may conjecture the *Animalcula* abounding in the purulent Matter flowing from the small Ulcers in that Distemper are of a different Species, Shape and Magnitude, from those of the Itch, they are not capable of insinuating themselves into the external Pores of many other Parts of the Body, so easily as into those of the secret Parts, which are large, *&c.*

### *Not All Distempers are of Microbic Origin.*

But I would not be understood to advance that all Distempers are caused by them; I would urge only the possibility and likelihood of their being the Essential Cause of the Plague, Pestilential and other malign Fevers, Small Pox, and some other Diseases as well Chronick as Acute, and particularly of that dreadful one a *Phthisis* which is the peculiar Subject of these Papers.

### *Rheums Predispose to Infection with the Organism of Phthisis.*

I have observed, that sometimes Coughs which seem to threaten an immediate Consumption, cease almost of their own Accord without that Consequence, and leave the Patient in perfect Health. ..... Now if what I have advanced may be allow'd the Reason of this is very plain, because if the body be ..... entirely free from such species of *Animalcula* or very minute Animals, that I imagine to be the Essential Cause of a Phthisis, that Disease, though the Cough is very violent or severe, will not happen: but if on the contrary, the Blood and Juices be charged with such noxious *Animalcula* ..... then a slight Cough may be succeeded by that most dangerous Distemper.

### *The Means by which the Organism of Phthisis enters the Body.*

If the Air we breathe, the Food we eat, or Liquor we drink in common with the rest of Mankind, were full of such minute living Creatures, or their Seed, then we might reasonably suppose that all Persons Breathing, Eating, and Drinking of the same, would in like Manner more or less be liable to the same Distemper, which would in that Case become Epidemical and almost Universal, this therefore we may imagine to happen in the Case of Plagues and Pestilential Distempers, that seize upon whole Cities Towns and Countires, at a Time, but not very likely in the Case of the Disease we now treat of (i.e., Phthisis).

It seems much more probable that the minute Animals or their Seed, which we have suppos'd to be the Essential Cause of a *Phthisis* or Consumption of the lungs, are for the most part either convey'd from Parents to their Offspring Hereditarily, or communicated immediately from distemper'd Persons to sound Ones who are very conversant with them; the first way has been already mentioned, when we were speaking of the Small Pox. ..... The last way, which is properly call'd Infection, we may conceive to be the more reasonable, if we consider how quickly and easily some other Distempers are communicated from one Person to another, as the Itch, Venereal Disease etc., which are yet very far from becoming universal.

It may be therefore very likely, that by an habitual lying in the same bed with a Consumptive Patient, constantly Eating and Drinking with him, or by very frequently conversing so nearly, as to draw in part of the Breath he emits from his Lungs, a Consumption may be caught by a sound Person; for it may be reasonable to suppose that if the Blood and Juices of such distemper'd People, be charg'd with vast quantities of *Animalcula*, as I have conjectur'd, then their profuse Sweats, and their Breath also, may be likewise charg'd with them, or their *Ova* or Eggs, which by that means may possibly be convey'd into the Bodies of those who lie, or are most conversant with them.

It may here probably be objected, that if the Disease is communicated after this Manner, few that come near a Consumptive Person would escape having that Distemper; but in Answer to this I imagine that slightly conversing with Consumptive Patients, is seldom or never sufficient to catch the Disease; there being but few if any of those minute living Creatures or their Eggs communicated in slender Conversations, and which, if they are, may not perhaps, be produced into Life, or be nourished or increased, in the new Station they happen to be cast; besides, we may imagine that some Persons are of such an happy Constitution, that if any of the *Ova* of the inimicable minute Animals that cause a Consumption, happen to get into their Bodies, they may likewise be quickly forc'd out again, through some of the *Emunctories*, before they are produc'd into Life; or else be wholly destroy'd.

### *Metastatic Processes Explained.*

I have already hinted, that most Animals, both of the Air and Water, delight to keep in distinct Species, and are found together in Swarms and Sholes; hence it may be suppos'd that the sudden Translation of some Distempers from one Part of the Body to another, may happen, by some Species of *Animalcula*, that I have conjectured to be the Prime Cause, suddenly removing themselves from the Part they first delighted, or chanc'd to fix in, and most injured, (either by some dislike through Remedies directed to that Part particularly, or some other means) to another, that before was perfectly well.

We may imagine that our Fluids, having great Numbers of the Ova or Eggs of very minute Creatures floating in them, may not possibly be injured thereby, or not to any considerable Degree, until in some of our innumerable Vessels, they meet with a proper *Nidus* or Nest, so as to be produc'd into Life probably in the Shape of an exceeding small Worm, and that in this Form swimming or being circled about in our Juices, they may be able, by stimulating the fibrous Parts of the Blood, preying upon the new made Chyle, and obstructing and nestling in some of our small Vessels or slender Canals, to occasion a tickling Cough, Hectick Heat, and other Symptoms of an approaching Consumption.

They may possibly in length of time, cause larger Obstructions, so as to occasion Tubercles to arise in the Lungs, and as those Creatures, are capable of stimulating the Vessels they so obstruct, we may suppose the Tubercles, Knots or Swellings occasioned thereby, will increase in Magnitude proportionably quicker or slower, and be the sooner or later inflamed; according to which, the Consumption proves either Chronic or Acute.

### *The Nature of Secondary Infection in Phthisis.*

Now when these Tubercles come to Suppuration, or break, and become small Ulcers, it may not be unlikely that the minute Animals which Caus'd all the Mischiefs hitherto mentioned, may now in those Ulcerations, as in proper Places, assume a different external Shape from what they before had, and by their now different parts or Weapons, stimulate more fiercely, and inlarge those Ulcerations, wounding or gnawing the Mouths of the small vessels opening into them, and at length be able, in their new shape, to get into the Mass of Blood and other Juices again, there to act a Part different from what they did before, viz.: stimulate all the nervous fibres of our small vessels to a great degree, and occasion all the Rigors and Horrors we feel, in the beginning of the Fits of Putrid Intermitting Fevers; which Rigors etc., are succeeded by a quick Motion of the Blood, and an Intense Fever, being Nature's Effort (if I may be indulged in the Expression) to throw off her enemy, which at last she does. ..... The body then remains tolerably easy, till the Blood and Juices receive a fresh supply of them, from the Ulceration or Ulcerations in the Lungs, and in such large Quantities, as to be able to produce a new Fit.

Not only had Marten a clear conception of the nature of infectious diseases, but he also foresaw many pathological problems to which the development of that theory has given rise. He takes a very fair and balanced view of the hereditary factor in pulmonary consumption, and he makes suggestions for a theory of immunity. It is also remarkable that while he includes in his group of microbic diseases such

conditions as syphilis and rheumatism, he does not commit himself on the subject of cancer, though aware of the existence of organisms in the discharges from cancerous ulcers.

Marten quotes frequently from the writings of the microscopists whose wonders were then attracting all the scientific world, and the suggestion of his theory may be traced to a remarkable passage by Frederick Slare which, having appeared in 1683, antedated the discovery of bacteria by Leeuwenhoeck which is often referred to the year 1687. In the Philosophical Transactions, Vol. XIII., 1683, p. 93, is "An Abstract of a letter from Dr. Winckler, Chief Physitian of the Prince Palatine ..... to Dr. Fred. Slare ..... containing an account of a Murren in Switzerland." In a postscript to this letter Dr. Slare wrote as follows:—

"I lately received an account of Two Ingenious Travellers who assured me the contagion had reached their quarters on the borders of Poland, having Passed quite through Germany. ..... They told me the contagion was observed to make its progress dayly spreading near two German Miles in twenty-four hours ..... that it continually without intermission made progressive voyages and suffered no neighbouring Parish to escape: so that it did not at the same time infect places at great distances. They added that cattle secured at rack and manger were equally infected with those in the Field. *It were worth the considering whether this infection is not carryed by some volatile Insect that is able to make only such short flights as may amount to such computations.* For the account of the Ancients is very little satisfactory to this Age, who derive it from a blind putrefaction, from incantations of ill men, or from conjunctions of inauspicious Planets. *I wish Mr. Leewenhoeck had been present at some of the dissections of these infected animals, I am perswaded he would have discovered some strange Insect or other in them.*" (Italics by Editor.)

Marten's book appeared in 1720, but was dated "From my House in Theobald's Row near Red Lyon Square in Holbourn, Sep. 1st, 1719," and although a second edition, or rather reprint, appeared in 1722, the book seems to have attracted very little attention from the medical profession of the day, and there are certain indications that the demand which called for a second issue may have been a popular rather than a scientific one.

It is interesting to note how Marten (exactly like Pasteur many years later) used epizootics and the phenomena presented by scabies as an illustration of the parallel nature of the infectious fevers in man.

Information as to the life and personal character of Benjamin Marten is almost wholly lacking. He was not a Member of the Royal College of Physicians, nor does he seem to have been a graduate of either of the English universities. His Latinity was not of a high order, while all, or nearly all, the works from which he quotes were either in English or French, or were available in translations into those languages. He writes, however, a witty and racy English style, and had evidently read carefully the recent scientific literature which had appeared in the vulgar tongues.

I have been unable to find any other works of Benjamin Marten, though there were several contemporary authors bearing the same name. Information concerning so suggestive an author and one of such exceptional foresight would be very welcome, and may, perhaps, be elicited by this short account of his work.[2]

[2] A fuller account of Marten's book has been given by me in the issue of "Janus" for February, 1911.

WORKING-CLASS ORGANISATIONS AND SCHOOL CLINICS.—On March 4th Mr. George Lansbury, M.P., presided at a conference held at Caxton Hall, Westminster, of delegates representing 177 trade unions, independent labour branches, and other working-class organisations to consider the method adopted by the London County Council for dealing with the medical treatment of school children. On the motion of Mr. Pearce of the Hampstead Trades Council, seconded by Miss Benton, a resolution protesting against the present system adopted by the County Council of subsidising London hospitals for the medical treatment of school children was adopted. The resolution included a demand for the establishment of special centres supported by grants from the Imperial Exchequer and adequately staffed with medical men, including dentists and nurses. On the motion of Mr. T. W. Kelly, seconded by Miss MacMillan, it was proposed that all working-class organisations should withdraw their financial support from voluntary hospitals as a protest against this use of the hospitals by the London County Council. This proposition was, however, at the suggestion of the chairman, amended so that it should apply only to hospitals which had made contracts with the London County Council. The motion was then carried.

# THE QUESTION OF COMPULSORY STATE INSURANCE OF EMPLOYERS' LIABILITY UNDER THE WORKMEN'S COMPENSATION ACT, 1906.

BY ALBERT BENTHALL, F.R.C.P. EDIN.

THIS question is in the air, at present in a nebulous condition, without form, and void, but, as it will be of the greatest possible moment to the medical profession, it should be considered in all its bearings before condensation takes place, and it becomes tangible in the form of a Draft Act of Parliament.

For the proper consideration of the question the working of the present Act must be borne in mind, with its admitted faults and difficulties, so that the experience gained in the last 3½ years may be used to advantage in the formation of a scheme, certain to come sooner or later, and perhaps sooner than many expect. Compulsory insurance must take one of two forms: (1) that all employers shall be compelled to insure with a department of the State; (2) or only those who do not insure with an insurance company which has complied with the regulations of the Board of Trade, and which is therefore approved and accredited by the State.

To anyone conversant with the working of the Workmen's Compensation Acts of 1897 and 1906, and the losses which have been incurred by various insurance companies, who have in the past insured employers against liability under these Acts, there would appear to be many difficulties in the way of insurance by the State, unless the State is willing to sustain the immense loss heretofore made by insurers, and a large additional loss also. It is clear that the State could not exercise the intimate individual and personal attention to claims which has been applied by the various offices, also it could not attempt to select business or decline unprofitable risks. Here a large question arises. If every one has to insure with the State, the State will fix its own rates, and these might be absolutely prohibitory if there were no competition. On the other hand, if the present insurance offices of undoubted standing are allowed to continue their business they should be placed on all fours with the State, and the regulations applying to State insurance should be applied to them. I should like to point out some of the prominent defects of the present Act which entail unavoidable but perfectly useless loss to every one concerned—employers, those who insure them, and the workmen.

1. Notice of injury: (*a*) At present a medical certificate is not required. (*b*) Need not be sent in reasonable time. *Note.*—1. Any person claiming on a club has to provide a medical certificate, and any workman unable to work in consequence of accidental injury must require medical treatment. It would therefore be no hardship to require a short medical certificate on a form to be obtained at any post-office, to be sent with the notice of accident. 2. Notice of accident should be given at once if possible, but certainly within 14 days.

2. There is no power to insist in proper medical treatment being obtained. *Note.*—If a man is sufficiently injured to be able to claim under the Act he should be compelled to seek the advice and submit himself to the treatment of a qualified medical practitioner or attend at some hospital.

3. There is no method of determining whether a workman is fit or unfit for work, nor can the workman obtain his half pay if it is withheld except by expensive litigation, entailing heavy costs. *Note.*—Employers are therefore severely hit, and many *bonâ fide* injured workmen suffer.

4. There is no power of reference to a medical referee except by a judge's order or consent of *both* parties. *Note.*—It is a well-known fact that if one side has a doubtful case a medical reference is objected to, as it is considered better to threaten expensive proceedings, in the hope of getting a settlement.

5. There is no power of contracting out of the Act with the consent of a registrar by previously injured, diseased, weakly, or aged persons, who are thereby shut out from employment. *Note.*—An increasing number of persons are being thrown out of employment and become a charge on the rates when they are anxious and willing to do such work as is within their power.

6. The registrars have no machinery for obtaining the advice of medical referees when required to register or refuse

registration of settlement. *Note.*—Registrars have to accept or refuse registration of settlements, without any knowledge of the real facts, and they are often hoodwinked by mendacious statements made by one side or the other.

7. There are no uniform rules as to medical assessors sitting with the county court judges either as to their employment or their procedure. *Note.*—There is no obligation for a judge to call an assessor to sit with him, or to act on his advice, as to the medical points, if he has called one. There are no rules as to procedure: some medical assessors examine the man alone, some allow medical men acting on behalf of the employer and workman to be present.

8. There is no provision of consulting-rooms and appliances for the proper examination of workmen at county courts. *Note.*—It is impossible for any medical assessor to properly examine a workman in a bare room, without even a couch in many cases, without any appliances for making any test, and without authority to administer an anæsthetic for the relaxation of muscles.

9. There is no appeal from the decisions of medical referees, which are "final and conclusive." *Note.*—Various suggestions have been made as to an appeal, but the views are so discordant, and many impracticable, that I prefer to deal with the matter later, under the essentials of State insurance.

If the foregoing and other defects of the present Act were remedied, so that the *bôna-fide* workman could be sure of his half wages being paid immediately after notifying the accident, and the employers, and those who insure them, could be protected against fraudulent and exaggerated claims and heavy costs, compulsory insurance would be unnecessary except for those who decline to insure. If compulsory State insurance should be enacted I venture to submit that the following points would be essential in the interest of the public, the profession, employers, and workmen.

1. That the State must not be allowed to fix its own rates of insurance. It should be in healthy competition with accredited insurance offices of standing, otherwise employers would be heavily hit with no redress.

2. The State or registrars must have notice of injury within a fortnight on a simple form to be obtained at any post office, clearly stating the nature of the injury and signed by the medical attendant of the workman.

3. Medical practitioners in every district should be appointed as medical examiners, and they should examine and report on every notified case of accidental injury without delay.

4. If the report of the medical examiner should not be approved and accepted by the workman, acting under the advice of his medical attendant, the matter should be at once referred to a medical referee, whose decision should be final unless appealed from within seven days. This would be on all fours with the procedure as to lead and other industrial poisoning, which are reported on by factory surgeons, and referred to a medical referee when cases are in dispute.

5. The Employers' Liability Act should be repealed, so that the questions of law would be few, the only questions being whether the workman was able to work or not, and what work, if any, he was capable of performing.

6. No settlements should be allowed to be made by the State unless registered by a registrar of a county court acting on the advice of a medical referee.

7. The decisions of medical referees should not be "final and conclusive." It should be possible to appeal from their decisions, and this is a very difficult subject, and various suggestions have been made. (*a*) That three medical referees from neighbouring circuits should form a court of appeal—that is, they should examine the workman and report either in favour of or against the decision of the medical referee. (*b*) That as many more medical referees would be required than there are at present, many of their decisions would be certain to be appealed from, and the appeal should be to a medical board of hospital surgeons, nominated by the Home Office in each district. (*c*) That consulting surgeons should be appointed by the Home Office to examine and report on decisions of medical referees referred to them by county court registrars, whose decision should be "final and conclusive." This latter would be cheaper, as only one fee would have to be paid instead of three or more.

8. Lay inspectors would have to be appointed in every district, so that the State should be in touch with injured workmen to insure their having proper medical treatment and the obtaining of work as soon as they are able to do it.

9. Stringent penal clauses should be inserted, dealing with those workmen who malinger or exaggerate.

As there are many thousands of small employers who do not insure, and who have not the means of paying compensation if a claim is made on them, some kind of compulsory insurance is necessary, but if by the State, the State must be protected. Many other points will have to be considered, especially those relating to legal questions, which do not come within my province, but the above points closely affect the medical profession, which must in the near future be more largely employed in safeguarding the interests of their patients, or of employers, than even now; while when compulsory State insurance does come in one form or another the State will have to rely upon the medical profession for its protection against loss.

## THE SMALL-POX EPIDEMIC IN LONDON.

THE following is a brief account of the epidemic of small-pox in the east of London since its outbreak.

On Feb. 5th a girl named Annie L——, 12 years old, of Key-street, Mile End, was admitted into a general ward in the Mile End Infirmary, where there were some 60 other patients. She was suffering from an eruption with severe indisposition, which was thought to be chicken-pox. Her friends visited her daily. No suspicion of its being small-pox occurred until late at night on Feb. 20th, when the medical superintendent of the infirmary, being suspicious of the condition of two other patients in the ward, called in consultation Dr. A. F. Cameron of the South-Eastern Fever Hospital. These cases were diagnosed as small-pox, and attention was thus drawn to the girl Annie L——, when it was found that her disease also was small-pox. In the early morning of Feb. 21st these three patients were removed to the Joyce Green Small-pox Hospital. On the same day four other cases—an unvaccinated girl, aged 3 (since dead), a probationer nurse, a ward scrubber, and Sarah L——, aged 11, a sister of Annie L——, none of them vaccinated since infancy, were removed to hospital. Two sisters of Annie L——, viz., Leah, aged 15, and Rebecca, aged 8, were then found suffering from small-pox. Rebecca had been to school on Feb. 20th and 21st, so that the school became infected from that date. On Feb. 22nd Felix K——, aged 1 month, unvaccinated (since dead), and Theresa C——, aged 21, a probationer, unvaccinated since infancy, were taken to hospital.

On Feb. 23rd the following 11 cases were removed from the same ward of the Mile End Infirmary: a woman, aged 23, a nurse, vaccinated in infancy only; a woman, aged 35, vaccinated in infancy only; a woman, aged 43, vaccinated in infancy only (since dead); a girl, aged 4, vaccination doubtful; a woman, aged 54, vaccinated in infancy only; a woman, aged 49, vaccinated in infancy only; a woman, aged 22, vaccinated in infancy only; a woman, aged 45, vaccinated in infancy only; a girl, aged 4, vaccination doubtful; a woman, aged 51, vaccinated in infancy only; a woman, aged 46, vaccinated in infancy only; also another member of the L—— family, a man, aged 20, vaccinated in infancy only. There were also two cases, one each from Poplar and Pimlico. On Feb. 24th three cases were removed from the infirmary, viz.: a boy, aged 1¾, not vaccinated; a boy, aged 4, not vaccinated (since dead); and a nurse, aged 24, not vaccinated. On Feb. 25th six cases were removed, five being from the infirmary, viz.: a girl, aged 2¼, not vaccinated (since dead); a woman, aged 65, vaccinated in infancy (since dead); a man, aged 42, vaccinated in infancy; a girl, aged 16, vaccinated in infancy; a girl, aged 15, not vaccinated; and one case from outside the infirmary, viz.: a woman, aged 30, vaccinated in infancy only; also a case from Hackney. On Feb. 26th two cases were removed to the hospital, one from outside and one from the infirmary. The latter, however, was found not to be suffering from small-pox. The other case, a woman, aged 67 years, had previously been a patient in the infirmary and was discharged on Feb. 13th. She was vaccinated in infancy. There was one case from Bethnal Green. On Feb. 27th two cases were removed to the

hospital from the infirmary: a woman, aged 84, not vaccinated (since dead); and a nurse, aged 21, vaccinated in infancy only; also two from Hackney and one from Deptford. On Feb. 28th two cases were removed from the infirmary to hospital—viz., a girl, aged 12 years, not vaccinated; and a woman, aged 40 years, vaccinated in infancy (since dead); also one case from Bethnal Green and one from Leyton. On March 1st there were no fresh cases, but on March 2nd four new ones occurred—viz., one from Paddington, one from Shoreditch, and two from Whitechapel respectively, and another death took place. On March 3rd two fresh cases were received at the small-pox hospital—one from Whitechapel and a doubtful case from Shoreditch—and another death took place. On March 5th one death was reported, and two suspects under observation were discharged as being free from the disease. On March 4th, 5th, and 6th there were no new cases.

At the time at which we write there are 42 cases under treatment, and the boroughs from which cases have been received are Stepney, Poplar, Shoreditch, Bethnal Green, Deptford, Hackney (all in the East End of London), Paddington and Pimlico (in the West End), and Camberwell in the South.

On the notification of the first diagnosis of small-pox, the medical officer of health of Stepney, Mr. D. L. Thomas, traced the early history of the first case. It appeared that the girl Annie L—— was taken ill on or about Jan. 28th. No rash had then appeared, and she attended the receiving-room of the London Hospital. She visited there on Feb. 4th and 5th, and on these occasions she doubtless had a rash, for her case was diagnosed as one of chicken-pox. On Feb. 5th she entered the Mile End Infirmary, and remained in the ward until Feb. 20th, when her case was diagnosed to be one of small-pox. In the meantime patients had been discharged from the ward and many visitors had been. Her family was at once put under observation, with the result that her two sisters and a brother, immediately they developed the disease, were at once sent to the small-pox hospital. Mr. Thomas obtained the addresses of all the friends of each individual member of the L—— family, and investigated their condition of health. In the course of this investigation he found that on Dec. 1st, 1910, a pregnant woman in the neighbourhood of Bell-lane had a rash which the medical man in attendance had diagnosed as chicken-pox. He had called in another practitioner and both had agreed on this diagnosis. This patient miscarried. On Dec. 6th another medical man attended her until Dec. 12th. He observed the rash, but did not think that it resembled small-pox. This patient had several young children, but all of them were vaccinated and had no rash. The mother was ill nearly up to Christmas. A man lodging in the house was taken ill about Dec. 20th, a rash appearing a few days afterwards. He remained away from work until Jan. 16th. For three weeks he was hardly out of his room, and most of the time was in bed. A sister of his, in the same room, about Jan. 17th developed a similar rash, but was less severely ill. Both these patients were attended by a medical man, who regarded the disease as chicken-pox. About Jan. 21st this girl visited the L——'s house in Key-street, when the first notified case, that of Annie L——, occurred. As already noted, Annie L—— became indisposed about Jan. 28th and developed a rash by Feb. 4th or 5th, some 12 days after the visit of the girl from Bell-lane. It is therefore reasonably certain that the disease from which the pregnant woman then suffered was small-pox, and that it in all probability was the cause of her miscarriage. Her recently vaccinated children apparently did not take the disease, but it was communicated to her lodgers, of whom one introduced it into the house in Key-street, whence it ultimately found its way into the Mile End Infirmary. There the true nature of the disease was finally recognised; not, however, until some 60 patients in the wards, several nurses, and many visitors had been exposed to infection, not to mention the possible previous contacts in the receiving-room of the London Hospital.

As to the question of vaccination, Mr. Thomas states that seven children under 8 years of age were attacked, of whom two were said to have been vaccinated. These two had the disease in a very mild form, and hardly seemed deranged in health. Of the other five, who had not been vaccinated, four died. Of 14 cases between 8 and 30 years of age, 3 had never been vaccinated and 11 vaccinated in infancy; none revaccinated. Of 13 cases between 30 and 60 years of age, all had been vaccinated in infancy; none revaccinated. Two have since died. Two of the three patients over 60 years of age have died, making a total of 8 deaths up to March 8th. All had been vaccinated in infancy, but none revaccinated.

It will be seen that owing to the large number of "contacts" the outbreak got a good start. The gradually increasing severity of the cases seems to indicate a mild character of the infection at first, with an increasing infectivity as it passed repeatedly through different hosts. To limit the spread as much as possible, by getting early information regarding its outbreak among contacts, the addresses of all patients discharged from the Mile End Infirmary since Feb. 5th were taken and all have been visited daily, as well as the houses of all outdoor officials of the infirmary. The families of all the 60 patients in the infected ward were treated as contacts, and they also have been visited daily. The addresses of all visitors to the infected wards also have been ascertained and their homes visited daily. The names of the absentees from the three schools attended by the L—— children are furnished every morning by the teachers and their homes are at once visited. All in the infected wards, both patients and nurses, have been revaccinated. Finally, the families of all those who develop the disease after contact as visitors at the infirmary, &c., are taken to the Council's shelters and kept under observation. It is hoped that the outbreak has been successfully brought under control; but owing to the very widespread exposure to infection that occurred prior to the recognition of the disease great vigilance is still necessary. Great credit is due, however, to the intelligent energy and efficiency of the sanitary authorities in tracing the origin so far back and placing all avenues of its further extension at once under constant observation.

## THE TRANSVAAL MINING COMMISSION.

IN 1907 a Commission was appointed by the late Transvaal Government to inquire into mining conditions generally in the Transvaal, and to make recommendations, *inter alia*, for the protection of the health and for the safety of persons working on the mines. The Commission was unable to submit its final report until March last, but this was not accessible to the public until recently. While it is reassuring to find that the Commission generally considers that the health conditions on the mines have vastly improved in recent years, yet there is evidently great need for further improvement, and the long list of recommendations prepared by the commission call generally for immediate attention.

### *Mortality amongst White Miners.*

The death-rates from all causes for the three years 1905, 1906, and 1907 per 1000 white mining employees are returned as approximately 20·425, 16·953, and 18·869 respectively. These at first sight would appear satisfactorily low when compared with the figures for other countries, but unfortunately the general low death-rates conceal a very high mortality amongst a limited class (13 per cent.)—namely, rock-drillers. The general low death-rates are explained by the fact that the figures include surface-workers, who constitute from 54 to 58 per cent. of all employees and are an exceptionally healthy class; also because at least one-third of the disabled rand miners leave the country and die elsewhere; and, lastly, because during the war there was a practical cessation of mining operations and 50 per cent. of the present rock-drillers have never worked machine drills except on the Rand and since the war, and in their case sufficient time has not elapsed for full manifestation of the effects of occupational disease. These death-rates, however, when corrected for age-constitution, are greatly in excess (approximately 60 per cent.) of those amongst white non-mining males of 20 and over. The death-rate from phthisis, including miners' phthisis, at ages of 20 and over, which in 1905, 1906, and 1907 was 5·7, 5·09, and 6·13 per 1000 respectively, was more than six times greater amongst white mining males than amongst white non-mining males, whilst this proportion by no means represents the condition in the case of rock-drillers, from which class most of the white miners, who die locally from phthisis, are drawn. The death-rate from respiratory diseases other than phthisis amongst white mining males at ages of 20 and over

was 70 per cent. greater than amongst similar white non-mining males. Excluding all respiratory diseases, there appears to be an appreciably lower mortality "from all other diseases" amongst white mining males of 20 and over than amongst white non-mining males of the same age period, which is explained by the Commissioners as likely to be in part due to the fact that the white miners' high death-rate from respiratory diseases tends in a limited degree to decrease the numbers liable to other complaints, and to the further fact that when a person with chronic respiratory disease succumbs to an acute intercurrent non-respiratory ailment the older standing disease will usually appear in statistical returns as the cause of death.

*Mortality amongst Native Labourers on the Mines.*

In regard to natives the Commission records its opinion that in the case of those from the temperate regions of British South Africa, excepting Basutoland, there is a consistently low mortality quite comparable to that of white underground workers; those from the subtropical and malarial areas of Portuguese East Africa, south of latitude 22°, as well as from the Northern Transvaal, Rhodesia, and Basutoland, show much higher, but still comparatively moderate death-rates, while those from the purely tropical districts, Northern Rhodesia, British Central Africa, Quilimane, and Mozambique, show very high death-rates. In view of the importance of this subject little evidence appears to have been received, and as will be seen later the conclusions and statistics of the Commission cannot be accepted altogether without reservation. Two medical witnesses gave evidence to show that the death-rate amongst native mine workers, which was alarmingly high in 1902–1903, differs from that amongst white miners in being due much more to climatic than to occupational causes; it is pointed out, however, by the Commission that since 1903 very great improvements have been effected, not only in respect to methods and seasons of recruiting, but also in medical inspection, supervision, housing, diet, working conditions, and hospital accommodation, with the result that there has been a marked and steady decline in the native mortality. This decline in the native death-rate from disease, as well as the apparent influence of the climatic factor, is well illustrated in the following table taken from the report of the Commission:—

*Average Death-rate per 1000.*

| — | — | 1903-04 | 1904-05 | 1905-06 | 1906-07 |
|---|---|---|---|---|---|
| 1 | "Tropical natives." | — | 130·1 | 99·5 | 70·5 |
| 2 | All natives. | 54·9 | 44·1 | 40·3 | 30·8 |
| 3 | "Non-tropical natives" (south of latitude 22°). | — | 35·3 | 33·4 | 27·7 |
| 4 | Quilimane natives. | — | 163·9 | 71·6 | 96·5 |
| 5 | Mozambique natives. | — | 128·2 | 65·8 | 67·5 |
| 6 | British Central Africa natives. | 115·5 | 118·3 | 166·3 | 62·9 |
| 7 | Rhodesia natives. | — | 118·6 | 79·8 | 46·2 |
| 8 | East coast natives (south of latitude 22°). | — | 39·9 | 35·8 | 33·7 |
| 9 | Transvaal natives. | 24·7 | 38·6 | 36·0 | 22·8 |
| 10 | Cape Colony. | 15·3 | 17·2 | 19·8 | 14·2 |
| 11 | Natal and Zululand. | 19·0 | 12·8 | 14·9 | 11·6 |

The Commission remarks that compared with European standards the death-rate is still high, but little is known of the normal death-rates of many of the native tribes in their own homes, and, again, the migratory tendency of native labour has to be borne in mind. The report says:—

> Each batch remains a comparatively short time; this, of course, minimises the effect of unhealthy underground working conditions, but, on the other hand, it means that almost as soon as such a batch becomes inured to the climate of the Rand, it is replaced by raw boys on whom falls by far the heaviest incidence of sickness and mortality. ..... Fortunately the natives from tropical areas constitute only 7·3 per cent. of the total number, as against 12·15 per cent. from Cape Colony, 3·5 per cent. from Natal and Zululand, 9·10 per cent. from the Transvaal, and upwards of 60 per cent. from the east coast, south of latitude 22°. Moreover, investigation has shown that the high susceptibility of these tropical and sub-tropical natives is not a permanent condition, and that after a few months' acclimatisation and familiarity with mining work there is a marked decline in sickness and mortality. This process of acclimatisation is comparatively short in the case of east coast boys, but, as might be expected, it is less complete, slower, and accompanied by so great a wastage amongst boys from British Central Africa and North-eastern Rhodesia that recruiting from these areas is no longer allowed by the Imperial Government. From the Portuguese tropical districts of Quilimane and Mozambique recruits are drawn under the following very salutary precautions—viz., (1) selection with special care under medical supervision; (2) arrival on the Rand during the summer months only; and (3) no underground employment within one month of arrival. In practice these natives remain under medical observation in the compounds of the Witwatersrand Labour Association until, in the opinion of the medical officer, they are fit to be drafted to the mines. The outstanding feature of these figures and facts is the advisability of recruiting mine natives as far as possible from the temperate regions of British South Africa and of minimising the number drawn from tropical districts.

Whilst racial and climatic conditions undoubtedly appear to have exercised great influence on the mortality rates amongst the different classes of native mine labourers, it is a pity that these rates were not separated by the Commission to show the difference according to race in the case of underground and surface workers respectively, as it is well known that many native tribes in Natal, the Transvaal, and Cape Colony are generally averse to working underground, and it would seem likely that a relatively large proportion of workers from these areas may have been employed mainly on the surface. Moreover, it is notorious that in native areas in these territories "boys" are constantly returning ill, particularly with phthisis, from the Rand to die in their homes, whereas it would seem probable that the sick from other and more inaccessible areas would not be able to obtain the same facilities to travel owing to lack of railway communication, and would therefore be likely to die or to recover locally on the Rand. There is nothing to show whether the Commission considered these factors, but even accepting the death-rates as given in the report they are generally, notwithstanding the pronouncement of the Commission, appalling, for it must be remembered that the "boys" recruited are selected natives in the prime of life, and passed as medically sound before actually employed, and that signing on for only short periods they are consequently not so likely to die from miners' phthisis as Europeans employed continuously underground. About 80 per cent. of the total deaths amongst native mine workers are, according to the Commission, in the order of their importance, due to pneumonia, phthisis, tuberculosis, cerebro-spinal meningitis, enteric fever, and dysentery, whilst operating as indirect and predisposing causes are malaria, notably scurvy to a less extent, and perhaps ankylostomiasis to a limited extent, especially amongst East Coast natives. The pneumonia death-rate is about 40 per cent. of that from all causes, whilst tuberculosis of the lungs comes next with about 18 per cent. The death-rate from the latter disease would doubtless be higher but for the fact already alluded to, that in certain areas a large number of infected "boys" return to die in their own homes. At the present time the Rand is undoubtedly responsible for the increasing prevalence of tuberculosis in the kraals of many native tribes, a matter to which the Commission does not refer, though it is admitted in the report that the disease in native mine labourers is almost invariably found to have been contracted on the Rand.

*Recommendations of the Commission.*

Into the causes of the unsatisfactory death-rates, both amongst European and native workers, the Commission enters at some length, and it submits a long list of recommendations for the betterment of existing conditions. With these recommendations we can cordially agree, particularly that workers infected with tuberculosis should be excluded from further underground employment; that the provision of a constant supply of clean water for the purpose of preventing the inhalation of dust in connexion with rock-drilling, blasting, and lashing, should be rigorously insisted upon whenever and wherever developmental work is carried on, where the natural strata are not wet, and in every dry and dusty stope, and that with equal rigour miners should be compelled to make use of the water thus provided; that the floor and sides of the working place to a distance of 10 feet from the face, where rock-drilling is being carried on, be kept sufficiently damped to prevent dust being raised by the escape of exhaust air, and that the damping of dry and dusty rock be carried out, not only before lashing commences, but be repeated as often as necessary while lashing proceeds; that proper shelters for the use of native underground workers should be erected near the shaft heads; that in future the erection of back-to-back dwellings should be prohibited; that a specified standard quality of air should be insisted upon throughout mine workings; and that lastly, a

Government medical inspector of mines should be appointed.

*Insufficient Air-space in Native Compounds.*

The Commission apparently agrees with the provisions of the Coloured Labourers' Health Regulations Ordinance of 1905, and appears to be fairly satisfied with the accommodation provided for natives. It is on this point that the views of the Commission cannot be wholly endorsed. If we remember rightly, this was a matter which brought Dr. G. A. Turner, when medical officer of health for the Transvaal, into conflict with the mining interests. The air-space required under the Ordinance consists of 200 cubic feet only for each labourer occupying the premises when the full complement for the accommodation of which the premises are provided is present. Surely it would not be unreasonable to expect further improvement in the health of labourers if a more liberal scale of air-space was provided. The Commission apparently contemplates that the medical inspector of mines should be an officer of the Mines Department. If, however, a proper department is organised, it would seem preferable for the medical inspector to be attached to the latter department as a subordinate of the chief medical officer. Moreover, the supervision of the health of mine workers generally should be entrusted to the latter officer.

Jan. 30th.

# THE HEALTH OF THE ARMY IN 1909.

## III.[1]

*South Africa.*

THE force in South Africa was reduced from an average strength of 14,075 in 1908 to 11,784 in 1909. The health statistics show a marked improvement as compared with the previous year, and one that is still more satisfactory when compared with the quinquennial average; both the admission and constantly sick ratios were lower than for the troops serving at home. The admissions to hospital were 331·2 compared with 458·9 in 1904–08, the constantly sick were 19·29 compared with 30·17, and the deaths were 3·73 compared with 5·66 per 1000. It is noted that the numbers treated in barracks were larger than in the previous year, owing to a relatively large number of minor injuries and inflammation of connective tissue cases among the mounted troops, and of convalescent cases of malaria in men arrived from India. The chief military stations are Pretoria, Bloemfontein, Potchefstroom, and Wynberg (Cape Colony). Wynberg shows the highest ratio of admissions to hospital, due chiefly (as heretofore) to venereal disease. Enteric fever caused 91 admissions to hospital, being in a ratio of 7·7 per 1000, a satisfactory reduction on the quinquennial ratio of 18; of these cases 49 occurred at Pretoria. This is an improvement on the previous year, when there were 65 admissions from approximately the same number of troops. As has been the case in the last few years, the disease has been of a very mild character, and there was only one death. The sanitary officer states that during October and November a number of mild cases were admitted from Roberts' Heights, "characterised by a sudden onset, early appearance of a profuse and atypical rash, intense headache, injected conjunctivæ, and early defervescence, occasionally by crisis. A number of these cases failed to give an agglutination reaction with B. typhosus or B. paratyphosus A and B. Blood cultures proved sterile even when 5 c.c. of blood were taken from a vein." The report says that in former years this type of disease would, in all probability, have been returned as simple continued fever or influenza. The diagnosis of enteric fever would appear to be doubtful. At Middelburg, Cape Colony, there were 15 admissions between February and May; eight of these were men whose duties led them into special contact with the town where enteric fever was rampant. When introduced into cantonments the disease appeared to spread by contact infection, either in the barrack rooms or latrines. Flies were unusually prevalent and "a veritable plague. As Middelburg is served by a dry earth system of conservancy, the influence of the fly in transmitting infection where enteric fever is rife cannot be overlooked. There is no evidence to incriminate water- or milk-supplies." In another part of the report it is stated that "wherever the pail system is in use great attention is paid to the cleanliness of the latrines. Disinfection is systematically carried out, which among other results has a marked effect in keeping down the number of flies." It would appear that Middleburg, for some reason or other, did not experience this benefit of latrine disinfection, the reason not being given. The occurrence of a number of very mild or doubtful cases naturally tends to a decrease in anxiety in regard to their importance, but an exacerbation of the type must always be considered possible. Malaria caused 133 admissions, of which 102 were recurrent attacks of disease contracted elsewhere; of the primary attacks 27 occurred at Pretoria. There was an unusually heavy rainfall early in the year, and, we are told, "water remained in pools and old quarries in the vicinity of the barracks well into the winter months. Mosquitoes increased in numbers, and anopheles became distributed over a wide area, including the whole of Pretoria, artillery barracks, and the cantonments, Roberts' Heights. Several cases of malaria occurred among the civil population in the town, and in March the municipal authorities took stringent measures to lessen the prevalence of mosquitoes. Early in April mosquito brigades were formed, who drained the pools, if reasonably feasible, and paraffined the water in all other instances. The result was an almost immediate cessation of the disease." Another good instance of effective prophylaxis was afforded on the arrival of troops from India. In anticipation of malarial incidence arrangements were ready in advance for their systematic treatment, frequent medical inspections were made, and quinine administered. Pyrexia of uncertain origin caused only 13 admissions, compared with 118 in 1908; the average number constantly sick was only 1·30; that is, one quarter of the sickness (or, in the phraseology of the writer of this report, "four times less than") in 1908. The decrease is principally due to careful bacteriological investigation carried out in all atypical cases of fever. Of the pneumonia cases nearly half (17) occurred at Bloemfontein, where rheumatic fever was also more prevalent than elsewhere; it is stated that no reason can be assigned for this. Sore-throat and tonsillitis have been much less frequent than usual during the past year. For venereal diseases, taken as a whole, there is a very slight decrease in the admission ratio, compared with the quinquennial period, though the figures are rather higher than those for 1908. Syphilis shows some improvement. Wynberg, Cape Colony, still has the highest incidence, owing to its proximity to Cape Town, though there is a reduction on the previous year's figures.

Sanitation continues to receive considerable attention, and we quite believe that "in barracks, on the march, in camp, and at manœuvres, every reasonable effort was made to attain the best results." Inoculation against enteric fever was extensively carried out, especially in regiments recently arrived from India. No extensive sanitary works were put forward during the year, it being felt that the political changes involved in the closer union that now exists between the South African provinces would have some effect on the distribution and strength of the garrisons. During the year the troops were removed from Middelburg, Cape Colony, a few details only now remaining. The water-supplies are generally noted as satisfactory, except at Pretoria and Potchefstroom, where they are boiled. At Roberts' Heights and the Artillery Barracks, Pretoria, B. coli is occasionally present even in one cubic centimetre of the water. "As noted in previous reports the health statistics show no relationship between the incidence of enteric fever and the pail system of conservancy. Where the water system is in most extensive use—Roberts' Heights and Artillery Barracks, Pretoria—the prevalence of enteric fever is much greater than in any other station in the command." This statement, however, as to absence of connexion between methods of excretal disposal and enteric prevalence is not consistent with the evidence of the report itself. As just mentioned, at Roberts' Heights and the Artillery Barracks the water is bacteriologically very impure (it is true that it is "boiled"); it is at least possible that the high enteric incidence in these barracks is due to the use of infected water for drinking, in which case it would have no connexion with the water-carriage method of sewage disposal. Moreover, on a previous page had been mentioned the coexistence of an enteric fever outbreak at Middelburg with

[1] No. I. and No. II. were published in THE LANCET of Feb. 25th (p. 534) and March 4th (p. 607), 1911, respectively.

employment of the dry-earth system and great prevalence of flies. The use of khaki drill, which was substituted for serge in 1908, is stated to have, so far, proved suitable and satisfactory.

*India.*

The average strength of the European force serving in India was 71,556, an increase of some 5000 troops over the garrison of the year preceding. The health statistics show a marked improvement on those for the previous year, and on the quinquennial averages. The admissions were 716·9, the constantly sick 40·26, and the deaths 6 37 per 1000; the corresponding figures for 1904–08 having been 839·1, 50·68, and 10·07. The returns for 1909 are the best that have ever been recorded, and the improvement has been noticeable under all heads. The invaliding ratio has come down to 9·06 per 1000, that for the preceding quinquennium having been 25·31. The more important causes that have conduced to these results are considered to have been (1) the steady improvement in the sanitary condition of cantonments; (2) the greater interest taken by commanding officers and others in the sanitary condition of latrines and barracks; (3) an increased appreciation on the part of the men of the value of a rational mode of life, and an intelligent perception of the elementary principles of hygiene; (4) the provision of steam disinfectors in various large garrisons, and a greater attention to the details of prompt and adequate disinfection of bedding and clothing; and (5) an enhanced appreciation of the benefits of anti-enteric inoculation, together with increased efforts by medical officers to detect mild or ambulant cases of enteric fever that formerly escaped notice.

The enteric fever statistics are most satisfactory: the admissions were 8·9, compared with 15·8 in the preceding quinquennium; and the deaths, 1 58, compared with 3·10; the number constantly sick was 2·06 as against 3·11; in all respects therefore, frequency of infection, fatality, and severity of attack, the improvement is most notable. The stations that suffered most were Meerut (26·1 admissions per 1000), Lahore (26), Kirkee (26), Lucknow (23·2), Sialkot (20 7), Multan (20·3), Jullundur and Dinapore (20). At Lahore, Kirkee, Lucknow, and Dinapore there were considerable increases in the number of cases over the preceding year, though all of these stations have a bad reputation for enteric fever; at Meerut and Sialkot and Multan, there was some decrease in prevalence. At some stations that had been severely attacked in 1908—e.g., Peshawar, Rawal Pindi, Jhansi, Jubbulpore, and Secunderabad—there was very slight incidence in 1909. Some stations, formerly notorious for enteric fever, had no cases at all; such were Kasauli and Cawnpore. Some notes are furnished as to causation: at Lahore 23 cases occurred, the earlier ones traceable to drinking polluted water on the march from Ranikhet, the later ones due to contact infection. Similar infection on the march accounted for an outbreak in the Royal Field Artillery at Lucknow. At Peshawar infected latrines were thought to be the cause; the disease died out soon after the introduction of the wet system with the use of cresol solution. Milk is not thought to have been a cause of any importance. The scattered distribution of most of the cases militates against the carrier theory as regards the troops themselves; but it is suggested that carrier infection may take place in the bazaars, and it is pointed out that "although only 22 per cent. of all enteric cases are women, the proportion of females amongst chronic carriers is at least 82 per cent." Three cases of infection are recorded in nursing orderlies, one of whom had refused to be inoculated; and one in the person of a medical officer attending on enteric patients. Six cases of isolation of paratyphoid bacillus A are recorded. At Cliffden, near Murree, an outbreak of 11 cases among women and 12 among children occurred during June and July. Excellent work is being done at the two convalescent depôts for enteric fever patients. At Naini Tal, where the depôt was established in 1908, during the year 360 men were under observation; the urine and fæces were examined twelve times in each case, and in seven instances carriers of typhoid bacilli were detected—i.e., just under 2 per cent., which conforms to European experience. The Wellington depôt for Southern India was opened in June, 1909; 64 men have been fully examined and discharged. Ten men were discharged time-expired before a complete examination could be made; 49 men remained under examination at the end of the year. Three carriers were detected. These depôts are of great benefit to the patients themselves, and are doing immense good by the protection they afford to the army as a whole.

Reviewing the question of enteric prevention in India, it appears to us that the present position is very encouraging. Infection by polluted water is now comparatively rare; the instances noted of such infection on the march to Lahore and to Lucknow are regrettable, but will perhaps lead to increased care in the future; such occurrences are now very exceptional, and should be considered, we think, as in every case requiring strict investigation. Infection by latrines is now also quite exceptional, and presumably the dry-earth system has by this time entirely disappeared. Infection of nursing orderlies is also a thing of the past, now that inoculation is so widely practised; we suppose an orderly who refuses inoculation will no longer be employed to attend on an enteric fever case. The carrier problem is being dealt with effectually in barracks; the bazaar source of infection by female carriers certainly does present difficulties, but happily the venereal admission rate has fallen from 126·9 in the quinquennium 1904–08 to 67·9 in 1909; this reduction, together with the encouraging growth of temperance in alcohol throughout India, leads us to hope that carrier infection from this source will also diminish. Lastly, of the total force of 71,556, no less than 43,556 men have been inoculated; the figures, so far, indicate that the attack rate in the inoculated is about one-third, and the case mortality one-half, of the rates in uninoculated men.

Malaria admissions were at the rate of 202·8 per 1000, being more numerous than in the preceding quinquennium (171·9), but less than in 1908 (244 6). Preventive measures have been carried out zealously, both for extirpation of mosquitoes and by prophylactic administration of quinine; this latter was carried out in practically all stations during the malarial season. Opinions seem to differ as to the results.

*Smaller Stations.*

One or two points only will be alluded to in this last section of the report. A diminution of sickness in comparison with the preceding quinquennium occurred in each of the smaller stations; in the Straits Settlements the admission ratio was practically the same, and, compared with 1908, showed an increase. Malaria accounted for 394 admissions per 1000, compared with a quinquennial average of 299; it is attributed to excessive growth of jungle in proximity to barracks and presence of infected natives. The former is a removeable cause; no explanation is given why such an obviously insanitary condition was allowed to exist. In Jamaica malaria was prevalent among the Royal Garrison Artillery at Fort Nugent; they were mounting heavy guns in November, when the rainfall was excessive and the troops were mostly under canvas in the bush, where anopheles mosquitoes abound, and a malignant tertian fever prevails. "The work," we learn, "was considered of such importance to the safety of the island that it could not be discontinued." We were not aware that Jamaica was in any immediate peril, except from earthquake, and the mounting of heavy artillery would hardly have been an effective safeguard against this danger. In West Africa there has been a considerable decrease in malarial fevers as a result of the labour devoted to anti-malarial operations, and an improvement in health generally. Tower Hill and Mount Aureol are now practically free from fever. There were no deaths in the command; the quinquennial average mortality (1904–08) had been 14·91 per 1000. In contrast to the Jamaica experience it may be noted that in Mauritius there were only 99 admissions per 1000 for malaria, compared with a quinquennial average of 283; extensive drainage works had been carried out on land bordering on barracks at Curepipe, night marches were discontinued, and no camps were formed during mobilisation, the men being housed in barracks; as a result, no admissions for fever followed on the manœuvres.

A study of this admirable report shows with what diligence and skill the health of the British army is being cared for under every variety of condition, the facts and figures are very clearly arranged, and the report in every way is one of great interest and value.

THE death is announced of Dr. Friedrich Ernst, formerly director of the Medical Clinic of Zürich University, at the age of 82.

# MEDICINE IN THE ENCYCLOPÆDIA BRITANNICA.[1]

## III.—*Surgery.*

THE volumes A to J treat of many subjects of no little importance connected with surgery. Under Surgery we may include Anæsthetics, for anæsthesia is ancillary to surgery, and an interesting though brief account is given of the history of the subject. The chief anæsthetics are described, while the modernity of the section is shown by the fact that in the account of spinal analgesia the attitude taken by the writer represents very fairly the present position—namely, that the method has undoubtedly its uses and will take its due place in surgery, but what place that is has not yet been settled. All the objections that have been urged against it are described.

In the article on Aneurysm we are told that the old method of Antyllus with modern aseptic conditions is now sometimes employed. It is somewhat doubtful whether Antyllus excised the aneurysm; apparently he only tied the artery above and below. In the modern method the aneurysm is excised after ligature of the artery on each side of the aneurysm. Other articles are on Disease of the Bladder and Prostate, and on Diseases and Injuries of Bone. Here it was hardly necessary to refer to Barker's method of wiring a fractured patella, for it is now out of date, and we believe it is never used now even by Barker himself. Burns and Scalds are well described, and what may be called the home treatment is carefully given. We can hardly agree that skin-grafting probably does not hasten healing. The article on Cancer describes the various theories which have been put forward to account for morbid growths, and preserves a judicious impartiality between them. Naturally, it says that operation is at present the only treatment. Other articles of a surgical nature are on Carbuncle, Hæmophilia, Hæmorrhage, Hæmorrhoids, Hernia, Hydrocele, and Hydrocephalus, and they need no special mention. They are sound summaries of their subjects.

Perhaps the most important, so far as the lay public is concerned, of the surgical articles is that on Appendicitis; for, on the one hand, there are many who are unnecessarily frightened with the fear of suffering from this affection, and, on the other hand, there are even more who fail to recognise the vast importance of the early treatment of appendicitis. The writer in the Encyclopædia considers that there can be no doubt that the disease is more common than it used to be, though he adds that the explanation of the increased frequency is not yet forthcoming. We are told that in some families there is a strange predisposition towards it. This is often stated in the text-books, but we should like to have some definite evidence in support of it. Of course, cases do run in families sometimes, but the theory of probabilities will account for this. After the etiology the article goes on to describe the anatomy of the appendix, and a description of the chief symptoms of the disease follows. Then a very typical and graphic account is given of an attack of acute appendicitis affecting a school-boy, and the course which it probably followed is also described; and this will give a clearer idea to the mind of the non-medical reader than could have been produced in any other way. The previous mild attacks of "indigestion" passing away under the influence of an aperient, the sudden onset of the disease after the boy gets wet through or sits on cold ground when heated at play, the localisation of the pain in the right side of the abdomen, the flushed face, the rise of temperature, the quickened pulse,—all these are well described. The writer proceeds to discuss the question of treatment. He presents the arguments in favour of waiting for the interval and those in favour of immediate operation, and comes to the conclusion that the safest method is immediate operation in all cases, for, says he, "It is highly probable that if every available hospital surgeon were asked if he had ever had cause to regret having advised early operation in the case of appendicitis the answer would be 'No'; on the other hand, every surgeon would be able to record cases in which delay had been probably disastrous, which an early resort to operation would in all probability have prevented." This is a highly practical way of answering a difficult question. Catarrhal or relapsing appendicitis, we are told, may be due to the presence of "bolted," unchewed, or undigested food in the cæcum, and that these mild recurrent attacks may sometimes be got rid of altogether by attention to the teeth and care in eating. In the chronic forms of the disease the need for operation has been well put: "To carry about a diseased appendix is to run the constant risk of being laid up at a time most inconvenient, as when travelling or when staying in some place where skilled assistance is far distant or absolutely unobtainable." The difficulty in many cases of recognising the exact severity of an attack is well described: "The most serious cases are those in which the aspect, the pulse, and the temperature of the patient fail to give warning of a very advanced state of the disease. These are, indeed, the serious cases, and at present it must be confessed that we have no certain method of recognising them. These are the cases which offer the most powerful argument in favour of immediate operation." A good description is given of what may happen when an attack of acute appendicitis is allowed to take its course. The possibilities of perforation are described, the chance of limitation by adhesions is referred to, and the reader is made to understand how the pus may either burst into the general peritoneal cavity with a fatal issue, or may slowly make its way into one of the hollow viscera, or to the surface of the body. Many authorities will agree with the writer in the Encyclopædia that when an appendicitic abscess has been opened, and the diseased appendix presents itself, it should be removed, while if it does not present itself it is safer for the surgeon to abstain from making a determined search for it at the time. With this view, on the other hand, many authorities do not agree, our own opinion coincides with the writer's on the whole, that for the moment at least drainage is sufficient. The possible errors in diagnosis are mentioned, and it is pointed out that diagnosis is sometimes impossible without recourse to operation, and generally the other morbid condition which has been mistaken for it may be relieved instead. Perhaps the most important paragraph in the article is that which deals with the treatment that should be employed in the case of appendicitis if, for one reason or another, operation has to be delayed, for these instructions may very reasonably be followed by the friends of the patient if they are at a distance from medical aid and they wish to employ to the best advantage the time that must elapse before a doctor can see the patient. The instructions are simple: "The patient should be put to bed with his knees resting over a pillow and a large fomentation under oil-silk should be laid over the lower part of the abdomen. No food should be given beyond an occasional sip of hot water. Purgatives should not be administered, as this would be to set in movement an inflamed piece of bowel. If the case be not acute a large enema of soap-and-water with turpentine may be given or possibly a dose of castor-oil by the mouth. As a rule, however, it is unwise to set the bowels in vigorous action until the diseased appendix has been removed. No opium should be given." Here we see in this single paragraph all the essentials of what may be called the non-professional treatment of appendicitis. The rest in bed, the raising of the legs, the warmth locally, the absence of all food with the exception of a sip of hot water, the risk of purgatives, the utility of an enema, and, lastly, the danger of opiates, but we cannot help thinking that a little more stress might be laid on the danger in these cases of giving any sedative at all. As the words stand the friends might feel justified in giving chlorodyne, for instance, or some other patent preparation containing morphia or some similar substance, and the value of the directions might have been increased if the explanation had been given that to administer an opiate to such a patient before he had been seen and examined by a medical man would be to obscure greatly the signs of the case, and so to interfere possibly with the diagnosis. We have quoted fairly fully from this article, and we think it is more likely to be studied by the general reader of the Encyclopædia than any other surgical article in all the volumes, so we may express the opinion that the writer, who is, we believe, Mr. Edmund Owen, has very happily struck the mean between the treatise for professional readers and the ordinary article on health subjects intended for lay readers.

[1] Articles I. and II. were published in THE LANCET of Feb. 25th (p. 530), and March 4th (p. 609), 1911, respectively.

It is by no means an easy thing to present professional facts to non-medical readers; it is very easy to cause unnecessary fear and disquiet amongst those who have no real knowledge of medical subjects, and, on the other hand, to fail to give what can really be called an accurate picture of a disease and its treatment.

We think the publishers of the Encyclopædia are to be congratulated on the high standard of the purely surgical articles. The article on Gynæcology occupies some seven columns, and, so far as is possible within that space, gives such a presentation of the subject as may reasonably be put before lay readers. The accounts are necessarily extremely brief. Sufficient of the history of this branch of medicine is given to show the general progress that it has undergone, and the various diseases of the female generative organs are shortly described. Our present recognition of the fact that many general diseases are caused by dental affections has greatly increased our idea of the importance of due care of the teeth, and we are glad to see that the article on Dentistry is adequate and very suitable for its position in this work. The section on the filling of teeth describes the various methods that have been employed, and reference is made to porcelain restorations. We are told that if successfully made porcelain fillings are scarcely noticeable, but that their durability remains to be tested. The general principles of dentures are described and the modern methods are also mentioned. We agree with the writer that moveable bridge work, though more difficult to construct, is preferable to fixed work as it may be more easily cleansed.

## MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

*Opening of Meeting.*

THE provincial meeting of this association was held on Feb. 23rd at the Cardiff City Mental Hospital, by the courtesy of Dr. Edwin Goodall and the committee of visitors, under the presidency of Dr. John Macpherson. There was a good attendance of members and visitors. The serious business of the sitting was preceded by a luncheon in the large hall of the hospital, at the invitation of the Lord Mayor (Alderman Charles H. Bird), and among those present at the repast were the President (in the chair), the Lord Mayor, Alderman Morgan Thomas, J.P., Dr. G. H. Savage, Dr. Charles A. Mercier, Mr. E. Tenison Collins, Mr. H. F. Hayes Newington (treasurer), Dr. C. Hubert Bond (general secretary), Dr. R. Percy Smith, Dr. Alfred Miller (registrar), and Dr. T. Drapes (President-elect).

After the toast of "The King," the LORD MAYOR proposed that of "The Medico-Psychological Association of Great Britain and Ireland," coupled with the name of the President. He pointed out that the membership of the association was 700, and that its organ, the *Journal of Mental Science*, constituted a reflex of the most recent researches bearing on the specialty. An important part of the activities of the association consisted in awarding special prizes to assistant medical officers, granting certificates to mental nurses—of both sexes—and in other ways raising the status of all who were connected with the care and treatment of the insane. He concluded by extending a cordial welcome to the association in the name of the citizens of Cardiff.—The PRESIDENT, replying on behalf of the association, expressed gratitude for the city's kind hospitality, and remarked that, the function of the members being the care and treatment of the insane, it was necessary continually to educate themselves, and it was in pursuance of that aim that the opportunity of the visit to the Cardiff Mental Hospital was welcomed.

The PRESIDENT proposed the toast of "The Lord Mayor and Corporation," and expressed a high opinion of the new Mental Hospital, which was well worthy of emulation.—The LORD MAYOR, in replying, said that in constructing the hospital the aim had been to have an institution which should be worthy of the city and of the cause, one in which patients could be properly housed and cared for, and yield a fair proportion of cures. That fair degree of success he could claim had been achieved. A further aim had been to make the hospital, by means of an efficient staff and adequate laboratory accommodation, a centre of investigation, and already distinct scientific advances had been made. He hoped one result of the visit of the association would be to encourage the workers at the hospital and to show the ratepayers of Cardiff the wisdom of the course which had been pursued.

Alderman MORGAN THOMAS (chairman of the Cardiff Mental Hospital Committee) proposed the toast of "The Visitors," coupled with the names of Dr. George H. Savage, Dr. Charles A. Mercier, and Mr. E. Tenison Collins. He pointed with great satisfaction to the fact that the cures at the hospital had been 46·7 per cent. of the admissions. There was also much wisdom in using the word "hospital," for, as Dr. Goodall said when the matter was discussed, the aim was not merely to detain mental cases, but to cure them.—Dr. SAVAGE, Dr. MERCIER, and Mr. TENISON COLLINS each replied.

*Papers Read.*

At the scientific meeting in the afternoon, the first paper was a report of an exhaustive research by Dr. H. A. SCHÖLBERG and Dr. EDWIN GOODALL, both of the Mental Hospital. It was entitled "On the Wassermann Reaction in 172 Cases of Mental Disorder (Cardiff Mental Hospital) and 55 Other Cases (Cardiff Infirmary, &c.), with Historical Survey." The authors dealt with the work of Bordet and Gengou on complement-fixation and its application to the diagnosis of syphilis by Wassermann, and then reviewed the published statements on the subject since 1906. The paper set out in detail the results in general paralysis and other kinds of mental disorder, including dementia præcox, epilepsy, idiocy or imbecility with epilepsy, idiocy and imbecility, and various other kinds of mental disorders. The results were also given in the case of controls from syphilitic non-mental cases, for purposes of comparison. In addition, they set out the results obtained by the dilution and concentration of the human amboceptor. An important point dealt with in the communication concerned the absolute and relative frequency of the reaction in serum and cerebro-spinal fluid, and its variability in individual cases. They found that the reaction became negative during a remission of the symptoms in general paralysis of the insane in several cases, but considered that there was need for a more detailed investigation on that point. Other points brought out were the necessity for repeated examination, the diagnostic value of a positive reaction in the cerebro-spinal fluid, the value of the Noure-Apelt test, and the desirability of ascertaining the relative frequency of the reaction in cases of general paralysis with known syphilitic history as compared with all cases of that disease.—Dr. PARKER, in discussing the paper, said that in 10 cases in which "606" had been used there was no alteration in the reaction after treatment.—Dr. SAVAGE regarded the contribution as an epoch-marking one. The fact that one case in which the reaction was negative proved to be one of injury and not syphilis reminded him of a claim which had been made for compensation for injury, and in which the defence was that it was a disability due to the specific disease and not to injury. If it could be definitely established that the positive reaction to the Wassermann test meant the disease in question, such cases could soon be disposed of.—Dr. PERCY SMITH heartily congratulated the authors on their work. He had not the opportunity of laboratory work, and as his work was mainly clinical, he was glad to hear Dr. Schölberg say that there were cases in which reliance must be placed chiefly on the clinical aspect. He understood that there were cases of general paralysis in which, even late in the disease, there was a negative reaction, and also some in which in the early stage the Wassermann test was negative, although the physical signs might point to the disease, but in which a positive reaction only developed as the disease progressed. There could be no doubt that the test was a most valuable aid to diagnosis. He related a case in which there appeared to be all the typical symptoms of general paralysis, but in whom the Wassermann test was negative. There was no history of specific disease, but there had been a severe injury to the head. It was probably traumatic general paralysis. One case, which seemed to be general paralysis and in which there was specific disease, was given "606," and following that he had increased excitement and exaltation. But his physical signs still remained in abeyance. At the Berlin Congress on the Care of the Insane a paper was read showing that the Wassermann reaction was positive in

many cases of malaria, presumably those in which there was no syphilis.—Mr. E. FAULKS asked whether the authors had compared their results with the cell-counts in the cerebro-spinal fluid, and whether they would describe the details of the precipitation test.—Dr. SCHÖLBERG replied that cytological counts were not done.—Dr. GOODALL replied that the observers who made the test and the cytological count found that the results did not necessarily coincide.

Dr. R. V. STANFORD read a paper on the Production of Indigo in the Human Organism.—Dr. SAVAGE remarked that it was going rather far to say that there was no parallel to be traced between the presence of indican and the mental symptoms in a stuporose case.—Dr. GOODALL said he had been watching the work, and was of opinion that the whole matter was in a state of flux; there was no exact knowledge on the subject of the production of indigo in the urine. Indigo occurred in the urine in other states than constipation and obstruction in the bowel, in such state as marasmus, cachexia from carcinoma, phthisis, &c. The paper showed the need of the subject being taken up by skilled workers, qualified chemists, because those medical men who had made statements on the matter up to the present were not competent chemists nor physiologists. That applied especially to certain Italian workers. They said one could associate the presence of indigo in the urine with clinical conditions. But this research did not warrant that statement. A method of quantitative estimation did not exist, and Dr. Stanford was endeavouring to produce one.

Mr. TENISON COLLINS, gynæcologist to Cardiff Infirmary, read a paper entitled "Notes on Gynæcological Conditions coincident with Mental Disturbances," in which he showed the close connexion subsisting between the nervous and generative systems. The disorders of the latter in females were often accompanied by headache, epilepsy, insomnia, hallucinations, the cure of which was followed by disappearance of the disturbances. If abnormalities of the pelvic organs in the insane were treated, there was generally improvement in the state of health, and if the abnormalities were present before the onset of the insanity the mind would also improve in some of the cases. But operations upon the reproductive organs were inadvisable for the amelioration of the insanity alone. The selection of the proper cases for this must be done by the medical staff.

The concluding paper was read by Mr. R. L. MACKENZIE-WALLIS on Metabolism in the Insane. His investigation showed that there was but little difference in the metabolism of the insane in comparison with that of normal people; but there were differences in the products derived from cellular activity, especially in some forms of insanity. In this it was suggested that the ductless glands played a large part, as the effects of disease of those glands on the metabolism were well known.

*Account of Dinner.*

At the dinner in the evening at the Royal Hotel, Cardiff, Dr. MACPHERSON proposed the toast of "The City and Port of Cardiff," and spoke highly of the vigour and wealth of the city and its progressive and enlightened policy. Nowadays people were not so much asking how rich the rich were, but what they were doing with their riches. If there were slums in Cardiff their parks and open spaces formed an excellent set-off to them. The Mental Hospital was unique in its efficiency and in the work it was doing.—The LORD MAYOR, in his reply, said the thanks of all Cardiffians were due to Dr. Macpherson for his kind words; they were proud of their city and of its trade, which was a very large one. They felt great pride in having had a visit from such an association.

Dr. SAVAGE proposed the toast of "The Mental Hospital Committee," coupled with the names of Dr. Goodall and Alderman Morgan Thomas, and spoke of the high quality of the work being done at the hospital in the attempts to advance the knowledge of mental disease.—Mr. Alderman MORGAN THOMAS, in responding, spoke of the excellent work being done at the Mental Hospital by Dr. Goodall and his staff, and said he believed that general hospitals ought to be supported out of the rates. The old idea in regard to diseases of the mind was that when once a person went into an asylum he or she was doomed, as far as this life was concerned. But better ideas now prevailed, and the old heathenish idea of mere detention had long been discarded. He saw no reason why diseases of the mind, provided they were not chronic, should not be as curable as those of the body.—Dr. GOODALL also responded, and expressed his belief in the German system of cliniques, whereby a patient was investigated from the standpoint of all the specialties—that of the mind included—and treated as his case was found to require. The staff and the board of management would feel in the visit of the association an incentive to continue their work with even increased enthusiasm, so as to add their quota to the sum of scientific knowledge.

Dr. MERCIER proposed the toast of "The Visitors," coupled with the name of Dr. Maclean; and that gentleman replied.

The toast of "The Medico-Psychological Association" was submitted by Mr. W. SHEEN, and he specially mentioned the welcome of local members of the medical profession.

The PRESIDENT of the Association, Dr. MACPHERSON, replied in a graceful speech, in which he bestowed high praise on the work being done at the Mental Hospital, and voiced the gratitude of the visitors for the reception they had enjoyed.

# VITAL STATISTICS.

## HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns 8121 births and 5040 deaths were registered during the week ending March 4th. The annual rate of mortality in these towns, which had been equal to 17·6, 17·2, and 16·2 per 1000 in the three preceding weeks, further declined to 15·3 in the week under notice. During the first nine weeks of the current quarter the death-rate in these 77 towns averaged 16·1 per 1000, and the mean recorded rate in London during the same period was 16·0. The annual death-rates during last week ranged from 5·6 in Handsworth, 6·2 in Hornsey and West Hartlepool, and 6·3 in Warrington, to 21·5 in Huddersfield, 23·9 in Sheffield, and 24·4 in Middlesbrough. The 5040 deaths from all causes in the 77 towns showed a further decline of 305 from the numbers returned in recent weeks, and included 663 which were referred to the principal epidemic diseases, against numbers increasing from 477 to 601 in the four preceding weeks; of these 663 deaths, 397 resulted from measles, 108 from whooping-cough, 64 from diphtheria, 53 (of infants under two years of age) from diarrhœa, 25 from scarlet fever, 15 from enteric fever, and 1 from small-pox. The fatal cases of measles, which had steadily increased from 160 to 359 in the first eight weeks of the current quarter, further rose last week to 397, they caused the highest annual death-rates of 3·2 in St. Helens, 3·8 in Coventry, 4·2 in Leyton, and 9·1 in Sheffield. The deaths from whooping-cough, which had been 132 and 91 in the two preceding weeks, rose again last week to 108; the highest death-rates from this disease last week were 1·6 in Norwich, 1·9 in Coventry, and in Stockton-on-Tees, and 2·4 in Middlesbrough. The 64 fatal cases of diphtheria also showed an increase upon recent weekly numbers, and included 25 in London and its suburban districts, 6 in Bradford, 4 both in Leeds and in Sheffield, and 3 in Cardiff. The 53 deaths of infants attributed to diarrhœa corresponded with the number in the previous week, and showed proportional excess in Smethwick and in Middlesbrough. The 25 fatal cases of scarlet fever were fewer by 8 than the number in the previous week; 6 occurred in London and its suburban districts, and 2 each in Handsworth, Leeds, Newcastle-on-Tyne, and Rhondda. The deaths referred to enteric fever, which had been 19, 16, and 14 in the three preceding weeks, were 15 last week, of which 2 each were recorded in Bristol, Birmingham, and Bradford. The fatal case of small-pox occurred in London. The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospital, which had 1276 and 1242 in the two preceding weeks, had further declined to 1197 on Saturday last; 129 new cases of this disease were admitted to these hospitals during last week, against 147, 166, and 138 in the three preceding weeks. These metropolitan hospitals also contained on Saturday last 918 cases of diphtheria, 682 of measles, 223 of whooping-cough, and 37 of enteric fever. The Metropolitan Asylums Hospitals contained 45 cases of small-pox on Saturday last, of which 16 new cases had been admitted during the week. The 1394 deaths from all causes in London last week, showing a further decline of 146 from the numbers in recent weeks, included 318 which

were referred to diseases of the respiratory system, against 421 and 395 in the two preceding weeks. In the 77 towns 153 deaths resulted from different forms of violence, against 163 and 173 in the two preceding weeks, and 381 inquest cases were registered. The causes of 47, or 0·9 per cent., of the deaths registered during the week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, Leicester, Stoke-on-Trent, Salford, and in 45 other smaller towns; the 47 uncertified causes of death in the 77 towns last week included 7 in Liverpool, 4 in Gateshead, and 3 each in Rochdale, Blackburn, Preston, Sheffield, and Hull.

### HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 898 births and 621 deaths were registered during the week ending March 4th. The annual rate of mortality in these towns, which had been equal to 19·8, 19·0, and 17·4 per 1000 in the three preceding weeks, further declined to 16·9 in the week under notice. During the first nine weeks of the current quarter the death-rate in these towns averaged 17·0 per 1000, and exceeded by 0·9 the mean rate during the same period in the 77 English towns. The annual death-rates last week in the eight Scotch towns ranged from 8·8 in Paisley and 14·0 in Aberdeen to 19·7 in Greenock and 20·1 in Dundee. The 621 deaths from all causes in the eight towns last week showed a further decrease of 20 from the numbers in recent weeks, and included 57 which were referred to the principal epidemic diseases, against 68 and 76 in the two previous weeks; these 57 deaths were equal to an annual rate of 1·6 per 1000, the highest rates from these diseases being 1·9 in Glasgow and 2·1 in Dundee. Of these 57 deaths from the principal epidemic diseases, 32 resulted from whooping-cough, 12 from diarrhœa, 5 from diphtheria, 4 from scarlet fever, 2 from measles, and 2 from enteric fever, but not one from small-pox. The fatal cases of whooping-cough, which had been 45 and 39 in the two previous weeks, further declined to 32 last week; they included 16 in Glasgow, 5 in Dundee, 3 in Edinburgh and in Paisley, and 2 in Aberdeen. Of the 12 deaths attributed to diarrhœa, including 10 of infants under two years of age, 9 were recorded in Glasgow. Four of the 5 deaths from diphtheria, and 3 of the 4 from scarlet fever also occurred in Glasgow. Both the fatal cases of measles were returned in Edinburgh; and of the 2 deaths referred to enteric fever 1 each occurred in Glasgow and in Greenock. The deaths referred to diseases of the respiratory system in the eight towns, which had been 181 and 139 in the two preceding weeks, further declined to 118 last week, exceeding by 5 the number returned in the corresponding week of last year. The deaths resulting from different forms of violence, which had been 22 and 21 in the two preceding weeks, were but 15 last week. Of the 621 deaths from all causes in the eight towns, 190, or 31 per cent., occurred in public institutions. The causes of 21, or 3·4 per cent., of the deaths registered during the week were not certified or not stated; in the 77 English towns last week the proportion of uncertified causes of death did not exceed 0·9 per cent.

### HEALTH OF IRISH TOWNS.

In the 22 town districts of Ireland, having an estimated population of 1,163,596 persons, 656 births and 455 deaths were registered during the week ending March 4th. The annual rate of mortality in these towns, which had been 24·1, 22·7, and 20·9 per 1000 in the three preceding weeks, further declined to 20·4, in the week under notice. During the first nine weeks of the current quarter the annual death-rate in these 22 towns averaged 20·8 per 1000, while during the same period the death-rate did not exceed 16·1 in the 77 English towns and in the eight Scotch towns 17·0 per 1000. The annual death-rate last week was equal to 21·6 in Dublin (against 14·8 in London), 17·4 in Belfast, 17·8 in Cork, 28·5 in Londonderry, 30·1 in Limerick, and 33·1 in Waterford; in the 16 smallest of the Irish town districts the mean annual death-rate last week averaged 19·3 per 1000. The 455 deaths from all causes in the 22 town districts last week showed a further decrease of 10 from the numbers returned in recent weeks, and included 41 which were referred to the principal epidemic diseases, against 29 and 25 in the two preceding weeks; these 41 deaths were equal to an annual rate of 1·7 per 1000, the highest rates from these diseases being 6·6 in Queenstown, 7·1 in Londonderry, and 9·6 in Sligo. Of these 41 deaths from the principal epidemic diseases, 22 resulted from whooping-cough, 8 from measles, 5 from diarrhœa, 4 from enteric fever, and 2 from scarlet fever, but not one either from diphtheria or from small-pox. The fatal cases of whooping-cough, which had been 11 and 10 in the two previous weeks, rose to 22 last week, of which 11 occurred in Dublin, 6 in Londonderry, and 2 in Sligo. Seven of the 8 fatal cases of measles, all the 4 deaths from enteric fever, the 2 from scarlet fever, and 3 of the 5 deaths attributed to diarrhœa occurred in Dublin. The deaths in the 22 towns referred to diseases of the respiratory system, which had been 141, 137, and 110 in the three preceding weeks, further declined last week to 108. Of the 455 deaths from all causes registered during the week under notice, 141, or 31 per cent., were recorded in public institutions. The causes of 23, or 5·1 per cent., of the deaths in the 22 towns last week were not certified either by a registered medical practitioner or by a coroner after inquest; the proportion of uncertified causes of death last week did not exceed 0·9 per cent. in the 77 English towns, and 3·4 per cent. in the eight principal Scotch towns.

## THE SERVICES.

### ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Staff-Surgeon: W. N. L. Cherry to Portland Hospital. Surgeons: H. M. Braithwaite to the *Vivid*, additional; C. D. Bell to the *Research*, on recommissioning; and A. Fairplay to the *Vivid*, additional, for disposal on the *Invincible* reducing.

### ROYAL ARMY MEDICAL CORPS.

Colonel G. W. Robinson has arrived home on leave from India. Lieutenant-Colonel M. L. Hearn has taken over the duties of Medical Inspector of Recruits in the Irish Command. Lieutenant-Colonel B. M. Skinner, M.V.O., has been appointed to the command of the Station Hospital at Rawal Pindi, in succession to Lieutenant-Colonel M. O'D. Braddell, transferred to Ahmednagar. Lieutenant-Colonel A. E. Morris has taken over charge of the Military Hospital at Cork. Lieutenant-Colonel H. D. Rowan, at present serving at Aldershot, has been selected to succeed Lieutenant-Colonel W. W. Pike, D.S.O., as Officer in charge of the Military Hospital at Tidworth Park. Lieutenant-Colonel R. G. Hanley, Dublin, has been placed under orders to embark for duty in South Africa. Lieutenant-Colonel W. A. Morris, commanding the Station Hospital at Cawnpore, has been granted six months' general leave in India with effect from April 17th. Major G. T. Rawnsley has been selected for appointment as Staff Officer to the Administrative Medical Officer of the East Lancashire Division at Manchester. Major R. F. E. Austin has been appointed a Specialist in Laryngology to the Third (Lahore) Division. Major G. St. C. Thom has been granted general leave for five months. Major C. H. Hale, from Stensall, has arrived in India for a tour of service. Major A. E. Smithson has been transferred from Wynburg to Pietermaritzburg. Major E. C. Anderson, D.S.O., from Kuldanna, has taken up duty at Rawal Pindi. Major G. F. E. Stammers has, on arrival in India, been appointed Sanitary Officer to the Fourth (Quetta) Division. Major E. B. Steel has been granted six months' general leave in India with effect from March 24th. Captain J. du P. Langrishe has been transferred from Poona to the Military Hospital at Kirkee. Captain F. H. M. Chapman, from Darjeeling, has taken up duty at the Station Hospital, Calcutta. Captain H. M. Morton, from Potchefstroom, has been posted for duty at Pretoria. Captain A. Dawson has been granted general leave for six months in India. Captain S. M. Adye-Curran has taken up duty as Specialist in the Prevention of Disease at Sialkot. Captain A. B. Smallman, on expiration of his tour of service in India, has been appointed to the Eastern Command and posted to Colchester. Captains W. C. Croly, J. T. Johnson, F. W. Lambelle, and J. E. H. Gatt have arrived in India. Captain M. H. Babington has arrived home on leave from Malta. Captain William G. Aviss resigns his commission (dated March 8th, 1911).

Lieutenant A. M. Pollard, on arrival in India, has been posted to the Second (Rawal Pindi) Division. Lieutenant V. P. Hutchinson has left the London District for duty in the Southern Command. Lieutenant W. R. O'Farrell has been transferred from Cairo to Khartoum for duty. Lieutenant A. D. Stirling, from Edinburgh, has joined at Piershill.

### INDIAN MEDICAL SERVICE.

His Excellency the Viceroy and Governor-General of India has selected Colonel G. W. P. Dennys, principal medical officer of the Derajat and Bannu Brigades, for the appointment of Inspector-General of Civil Hospitals in the Central Provinces, in succession to Colonel J. A. Cunningham, deceased. Lieutenant-Colonel H. H. B. Robinson has been appointed Residency Surgeon and Chief Medical Officer of Rajputana by the Foreign Department of the Government of India. Lieutenant-Colonel H. B. Melville, civil surgeon of Simla East, has been granted leave for one month and 15 days. Lieutenant-Colonel R. H. Castor, on return from leave, has been appointed to the Civil Medical Charge of the Shwebo District in succession to Lieutenant-Colonel F. J. Dewes, proceeding on leave. Major A. Leventon has been appointed Civil Surgeon of Lakhimpur during the absence on deputation of Lieutenant-Colonel E. R W. C. Carroll. Major H. J. Walton, civil surgeon of Bulandshahr, has been placed on Special Duty in connexion with the United Provinces Exhibition at Allahabad. Major G. Lamb, Bengal, has received an extension of his leave of absence from India for two months on medical certificate. Major J. Bowle Evans has been appointed Medical Officer of Health at Peshawar. Major R. G. Turner, civil surgeon at Saharanpur, has taken over duty as Civil Surgeon at Gonda. The Secretary of State for India has approved the grant of four months' study leave to Major F. A. L. Hammond. Captain C. Dykes has been appointed Civil Surgeon at Jaunpur, on return from leave. Captain E. J. C. McDonald has been posted to Jhelum, in succession to Captain S. B. Mehta, transferred. Captain L. Hirsch has taken over duty as Surgeon at the General Hospital, Madras. The services of Captain F. C. Rogers have been placed permanently at the disposal of the Government of Madras. Captain A. E. Grisewood has been appointed District Plague Medical Officer at Hoshiarpur, in succession to Captain H. Watts, proceeding on leave. Captain S. R. Godkin has taken over duty as Specialist in Advanced Operative Surgery to the Sixth (Poona) Division of the Southern Army. Captain R. McCarrison has been confirmed in his appointment of Agency Surgeon (Second Class) by the Foreign Department of the Government of India. Lieutenant M. D. A. Kureishi has been transferred from the Lahore Division to Rawal Pindi and appointed to the officiating medical charge of the 32nd Sikh Pioneers and the 28th Punjabis.

### SPECIAL RESERVE OF OFFICERS.

*Royal Army Medical Corps.*

Laurence Melville Routh to be Lieutenant (on probation) (dated Feb. 6th, 1911).

### TERRITORIAL FORCE.

*Royal Army Medical Corps.*

South Wales Mounted Brigade Field Ambulance, Royal Army Medical Corps: Major John R. I. Raywood to be Lieutenant-Colonel (dated Dec. 8th, 1910).

Welsh Border Mounted Brigade Field Ambulance, Royal Army Medical Corps: Lieutenant George Jubb resigns his commission (dated March 4th, 1911).

1st Lowland Field Ambulance, Royal Army Medical Corps: William Ferguson Mackenzie to be Lieutenant (dated Feb. 18th, 1911).

2nd Lowland Field Ambulance, Royal Army Medical Corps: Dugald Henry MacPhail to be Lieutenant (dated Jan. 4th, 1911).

*Attached to Units other than Medical Units.*—Major George Williamson resigns his commission, and is granted permission to retain his rank and to wear the prescribed uniform (dated March 8th, 1911). Lieutenant Alfred H. Godwin resigns his commission (dated March 8th, 1911).

*For attachment to Units other than Medical Units.*—Norman Mello Fergusson to be Lieutenant (dated Jan. 15th, 1911).

### CLEAN DRINKING CUPS ON BOARD SHIPS.

We have formerly (THE LANCET, vol. ii., 1909, p. 1761) noted the attention which is directed in the German and American navies to mouth disinfection and to the prevention of the spread of disease on board ships by drinking cups which are used in common. The *Archives de Médecine et Pharmacie Navales* for February (an old friend which has this year taken to itself a new name) tells us that this use of a common drinking cup by the men is in the French navy thought to spread diphtheria, tubercle, cerebro-spinal meningitis, influenza, and other infectious diseases, as well as syphilis. To avoid these risks Dr. Bonain (Médecin Principal de la Marine) has devised a mechanism which offers a clean, sterilised drinking cup to every man. The drinking cups are conical and fit into one another very closely. They are held ready in one of two cylinders which are arranged in pairs on the walls or water-tank near the taps. From one cylinder, which is locked, cups can be withdrawn by a pull; they cannot be returned here, but each man, after he has filled his cup and had his drink, returns the cup to the other cylinder, where it is held till the man in charge comes round, unlocks that cylinder, removes, washes, and sterilises the used cups by boiling. He then puts them back in the first cylinder again and locks it up. We welcome this device, which will do good if the men will use it, and use it they will if they are taught thoroughly to understand its importance.

### DEATH OF ADMIRAL SIR ASSHETON CURZON-HOWE.

By the sudden death of Admiral Sir Assheton Gore Curzon-Howe, G.C.V.O., K.C.B., C.M.G., Commander-in-Chief at Portsmouth, many naval medical officers have lost a friend they can with difficulty expect to replace. He manifested towards his subordinates an unusual politeness and consideration which made him beloved. From many medical officers we have heard of him, and have learned the impression that he conveyed to them at his official entertainments that he was himself glad to meet them, of his personal support to them in their work, and of the trouble that he and Lady Curzon-Howe took, when he was Commander-in-Chief at Malta, to see that the wives and families of medical officers whose ships were away cruising should not be forgotten. He is deeply mourned in the navy.

### OFFICERS TRAINING CORPS OF LONDON.

We have received the report of the Military Education Committee to the Senate of the University for the year 1910, which gives details of the strength and efficiency of the Officers Training Corps Contingent. Since its formation in January, 1909, the objects of this corps have been to provide students at schools and universities with a standardised measure of elementary military training with a view to their eventually applying for commissions in the Special Reserve of Officers or the Territorial Force. The full advantages of the training do not accrue until cadets have taken Certificate B, for which at least two years' service in the corps is required. Already 11 cadets have proceeded to commissions in the Army, five in the Special Reserve and six in the Territorial Force. The general administration of the contingent has been entrusted by the Senate of the University of London to a Military Education Committee, which hopes that in future a much larger number of cadets will proceed to commissions. A fourth section has been added to the medical unit owing to the large number of medical cadets at the Middlesex Hospital. The officers of the medical unit comprise Major W. P. Herringham, Major H. H. Tooth, Captain A. M. H. Gray, Captain R. Davies-Colley, Captain A. E. Johnson, Lieutenant J. C. Briscoe, Lieutenant T. B. Layton, Lieutenant G. C. Mathison, and Lieutenant W. V. Corbett.

---

A NEW HOSPITAL AT PUTNEY.—Sir William Lancaster, the chairman of the new Putney Hospital committee, points out in a recent issue of the *Times* that the late Mr. Chester bequeathed a sum of money which it is estimated will eventually amount to about £80,000 to provide the income for a general hospital to be built at Putney within 20 years of his death. Mr. Chester died about 10 years ago. The money required for building the hospital has been subscribed almost entirely locally, and the site has been given by a Putney resident. Sir William Lancaster hopes that the hospital will be ready for the reception of patients by the end of the summer. There will be 20 beds and a ward for children.

# Correspondence.

"Audi alteram partem."

## CHARLES BELL AND THE MOTOR AND SENSORY FUNCTIONS OF SPINAL NERVES.

*To the Editor of* THE LANCET.

SIR,—In regard to the somewhat ancient dispute whether Bell or Magendie discovered the motor and sensory functions of the anterior and posterior roots of the spinal nerves, it may be of interest to recall the courteous and generous manner in which Magendie dealt with Bell's claim to priority. In his second article, entitled "Expériences sur les Fonctions des Racines des Nerfs qui naissent de la Moelle épinière," Journal de Physiologie Expérimentale et Pathologique, 4e Numéro, Octobre, 1822 (the first article appeared in the same journal in August, 1822), he says:—

Avant de terminer cet article, je dois donner quelques éclaircissements sur la nouveauté des résultats que j'ai annoncés.

Quand j'ai écrit la note contenue dans le numéro précédent, je croyais être le premier qui eût songé à couper les racines des nerfs spinaux; mais je fus bientôt détrompé par un petit écrit de M. Schaw (Shaw) que ce jeune et laborieux médecin eut la complaisance de m'envoyer dès qu'il eut reçu le numéro de mon journal. Il est dit dans cet écrit que M. Ch. Bell avait fait cette section il y a treize ans, et qu'il avait reconnu que la section des racines postérieures n'empêchait pas les mouvements de continuer. M. Schaw ajoute que M. Ch. Bell avait consigné ce résultat dans une petite brochure imprimée seulement pour ses amis, mais non pour la publication. J'ai aussitôt demandé à M. Schaw qu'il voulût bien m'envoyer, s'il était possible, la brochure de M. Ch. Bell, afin que je lui rendisse toute la justice qui lui serait due. Peu de jours après je l'ai reçue de M. Schaw.

Cette brochure a pour titre:

"Idea of a New Anatomy of the Brain, submitted for the Observation of his Friends, by Ch. Bell, F.R.S.E."

Magendie goes on to say:—

Elle est très-curieuse en ce qu'on y remarque le germe des récentes découvertes de l'auteur sur le système nerveux.

He then quotes in full the passage ending:—

On laying bare the roots of the spinal nerves, I found that I could cut across the fasciculus of nerves, which took its origin from the posterior portion of the spinal marrow without convulsing the muscles of the back; but on touching the anterior fasciculus with the point of a knife the muscles of the back were immediately convulsed.

His comment on this is:—

On voit par cette citation d'un ouvrage que je ne pouvais connaître, puisqu'il n'a point été publié, que M. Bell, conduit par ses ingénieuses idées sur le système nerveux, a été bien près de découvrir les fonctions des racines spinales; toutefois le fait que les antérieures sont destinées au mouvement, tandis que les postérieures appartiennent plus particulièrement au sentiment, parait lui avoir échappé: c'est donc à avoir établi ce fait d'une manière positive que je dois borner mes prétentions.

It is clear from this quotation that Magendie admitted that Bell had anticipated him in the crucial method of dividing the spinal nerve-roots, but justly claimed that he, not Bell, established the fact that the function of the anterior roots is motor, and that of the posterior roots, sensory.

With all desire to give credit to Bell's masterly investigation of the functions of the cranial nerves, it must be admitted that Magendie rightly said that he was only "very near discovering the functions of the spinal roots."

I am, Sir, yours faithfully,

LEONARD GUTHRIE.

Upper Berkeley-street, W., March 3rd, 1911.

## THE MEDICAL BRANCH OF THE NAVY LEAGUE.

*To the Editor of* THE LANCET.

SIR,—May I ask for the hospitality of your journal again to draw the attention of the profession to the Medical Branch of the Navy League.

The object of the League is to enlist the interest of medical men throughout the country and to ask their help by their example and influence in keeping the country alive to the necessity of a strong navy. Without the absolute command of the sea our freedom and our national interests are in peril. Still less can we regard the imperial and colonial portions of the British Empire as secure. Twelve years ago we were able to transmit more than 100,000 troops and all the transport for an extensive campaign 6000 miles to the base of our operations without the mobilisation of a single extra warship, and this in face of the scarcely veiled hostility of two, if not three, first-rate Powers. Such at that time was our naval prestige that the millions necessary for such mobilisation were spared. Would it be so to-day?

Each medical man has much influence in his own locality, and can do much by himself joining and inducing his friends to join in the League, which is a strictly non-political body and has for its object the advocacy of a strong navy to safeguard that security which forms an essential background to all advance in commerce, science, and the social conditions of the people. I would point out that to be a member of the League a five shillings' annual subscription is all that is necessary; it is the influence and advocacy that is wanted much more than money.

I am, Sir, yours faithfully,

R. DOUGLAS POWELL,

March 5th, 1911. President of the Branch.

PS.—All who desire to respond to this invitation to join should send their names to the secretary, Medical Branch of the Navy League, 54, Welbeck-street, W.

## THE TREATMENT OF MALIGNANT STRICTURE OF THE ŒSOPHAGUS, WITH ESPECIAL REFERENCE TO INTUBATION AND TO RADIUM.

*To the Editor of* THE LANCET.

SIR,—On Feb. 13th, Dr. W. Hill read a paper at the Medical Society on the above subject, and in the discussion which followed I ventured to give some of my own experiences which the author of the paper criticised in your issue of March 4th. May I briefly reply to these and answer his last criticism first of all?

It must have been quite obvious to all present that Mr. Bellamy Gardner's anæsthetic tube could only be used with the bronchoscope, and that I was thinking of this and unintentionally wandering from the subject (œsophagoscopy) under discussion. I am, however, much obliged to Dr. Hill for pointing out this mental slip, if only because it affords another opportunity of bringing to notice Mr. Gardner's excellent little device for administering chloroform during bronchoscopy in such a way that the surgeon's view through the tube is not obstructed. I am quite sure with Dr. Hill that, in spite of all the advances made in the administration of anæsthetics, rectal and otherwise, neither "Mr. Bellamy Gardner nor any other anæsthetist in his senses would dream of administering a general anæsthetic *through the œsophagoscope*, not even in those cases where there is a communication between the gullet and the air passages." The anxious author of the paper may rest well assured that I do not propose casting any burden on the gullet beyond those it already has to bear.

Dr. Hill strongly dissents from my view that chloroform is the best anæsthetic when general narcosis is considered desirable in direct œsophagoscopy. I believe, Sir, that the whole object of such discussions as he introduced is to elicit the opinions, based upon experience, of those who may have worked at the subject-matter of the debate. That being so, I have only to say that if a patient be carefully prepared (including, if it be thought desirable, the previous injection of morphia and atropine), and the services of an expert anæsthetist can be obtained, my experience has led *me* to prefer chloroform, and so far the record of a considerable experience has not been sullied by the "occasional disaster" which Dr. Hill warns us may "be not unlikely" if that drug be alone used. On the other hand, I am quite willing to believe that Dr. Hill's anæsthetists can get equally good results and satisfy his requirements when ether alone or chloroform and ether are used—obviously this has been *his* experience and is shared by some others.

I am sure Dr. Hill will agree with me that the best anæsthetic is that which gives to the individual worker the best results, and the choice will largely depend on those subtle and varying factors which go to the making of individual experience.

I am, Sir, yours faithfully,

Harley-street, W., March 6th, 1911. HERBERT TILLEY.

## THE SPHYGMOMANOMETER AND THE SPHYGMOGRAPH IN RELATION TO THE MEASUREMENT OF ARTERIAL BLOOD PRESSURES.

*To the Editor of* THE LANCET.

SIR,—Dr. C. O. Hawthorne has, I think, done good service to sphygmometry in publishing his address in your columns on "The Sphygmomanometer and the Sphygmograph in Relation to the Measurement of Arterial Blood Pressures."[1] I quite agree with him that the "time" element in the cycle of arterial pressure is lacking in the sphygmometer employed *à la* Riva-Rocci; and in fact any one-point observation of that cycle, whether indicated by the criterion of maximum oscillation of the mercurial column, or that of reappearance of the pulse after its obliteration, must be less or more misleading. The result of all my observations on the measurement of arterial pressure points to the conclusion that the pressure cycle should be read at no less than two points. But my recent studies on the auditory method of determining the arterial pressure[2] show that by its aid the entire cycle can be measured; therefore we must regard the adoption of this method as an important step in the evolution of the sphygmometer.

I am, Sir, yours faithfully,

Farnham, Feb. 25th, 1911. GEORGE OLIVER.

## THE LANTERN TEST FOR COLOUR BLINDNESS.

*To the Editor of* THE LANCET.

SIR,—I should be very sorry if anything in my letter was unfair to Dr. Edridge-Green, but in justice to myself I must point out that I began my experiments with my lantern as far back as three years after my appointment to the Western Ophthalmic Hospital, which was in 1884. So that I certainly did not crib my idea from Dr. Edridge-Green. I did not know that his lantern was now in use at the Admiralty, but I had a visit some little time back from Fleet-Surgeon Collingwood—then in charge of the recruiting station in Whitehall—and he told me he was just getting another of my telechromes fitted up similarly to the one in use in Victoria-street.

I find no difficuity in using wools and the telechrome if a sheet of some opaque material is hung across the room or passage where the lantern is placed. There is a hole in the sheet, and the candidate looks through the hole at the lantern, while he himself remains in daylight with the wools on a table before him. The colours in my telechrome may not satisfy Dr. Edridge-Green, but I have found them quite sufficiently good to detect numerous cases of colour blindness, some of which had passed the Holmgren wool test alone quite easily; and I do not believe that any man who can pass my combination test as described in my previous letter would be a source of danger either in a ship or on a train. In conclusion, I must say I still prefer my own method of varying the illumination. I think, with all due respect, that increasing or decreasing the illuminant by moving a lever is simpler and better than the introduction of neutral-tint glasses. However, "chacun à son gout!"

I am, Sir, yours faithfully,

A. ST. CLAIR BUXTON.

Mansfield-street, W., March 6th, 1911.

## EYE-STRAIN IN RELATION TO GENERAL HEALTH.

*To the Editor of* THE LANCET.

SIR,—Mr. Kenneth Campbell in THE LANCET of Feb. 25th, p. 541, criticises Dr. James Hinshelwood's explanation of the reason for the discomfort to which small degrees of astigmatism give rise. In my opinion, the true explanation is that the discomfort arises because the error is so slight; the patient makes no effort to correct it, and therefore the brain pictures are blurred and their mental interpretation requires the employment of more nerve force. If it were a pure case of muscle fatigue compensatory hypertrophy ought to counterbalance it, and the rule of the smaller the error the greater the discomfort would be exactly the reverse of what we know is really the case.

Refractive errors give rise to brain-fag and eye-strain. The latter is really much the rarer and is associated with efforts made to balance mal-adjustments of the eyes in binocular vision and long sight when of *medium* amount. Brain-fag arises from congestion of the high visual centres owing to the difficulty of interpreting "slightly fogged" pictures and unequal visual representations, and leads to anæmia of other centres and the various organs which demand a good blood-supply. One has only to recall the effect of mental concentration on the hearing centre, on digestion, and on the circulation of the hands and feet, to understand how effects can be brought about by a "mental circulatory congestion of the visual centres." High errors of refraction do not produce the same effects because the sensitive portions of the retino-cerebral tract are less finely developed. They produce an effect only when one meridian is emmetropic—viz., a doubly sensitive visual centre—and its results become manifest in the next generation who inherit a hypersensitive nervous system. These theories can be confirmed by careful observation and show the great need which exists for correcting all errors of the eyes at the earliest possible age in life. Their influence in these days of education accounts for a large number of the so-called cases of neurasthenia. The subject is one too large for the space of a letter to discuss at any length, but one I hope to treat of at length on some other occasion.

I am, Sir, yours faithfully,

Manchester, March 2nd, 1911. A. A. BRADBURNE.

## THE MEDICAL SERVICE IN FRENCH THEATRES.

(FROM A CORRESPONDENT.)

IN France they manage some things better than we do in this country: "Le Service Médical dans les Théâtres" proves this, but not in a very convincing way, for, as we shall see, we have here a very good idea but one indifferently carried out. If any mishap occurs in a London house of entertainment and a medical man happens to be among the audience the sufferer receives immediate attention of a kind. The medical man who is present can render first-aid and give instructions as to the removal of the patient, but there is no obligation, statutory or otherwise, on the part of the management of a house of entertainment to make provision for any unforeseen event which may arise. Things are different in France, where theatres, cafés-concerts, and other public amusements are directly under the supervision of the police under powers dating from 1790. The last police ordinance is dated August 10th, 1908, and by it the supervision of the Prefecture of the Police starts before the building is erected. Of the various provisions laid down for the safety of the public those with which I am now concerned are the *service médical*. Article 227 enacts that every establishment of the first category (that is, theatres) and every establishment of the other categories (circuses, hippodromes, velodromes, cafés-concerts, and other analogous establishments capable of showing scenes and other accessories of the stage), constructed to accommodate 800 persons or more, shall provide a medical service. *Le médecin de service* at the first requisition must be upon the spot to render professional assistance not only to the spectators but to the *personnel* of the establishment. A room suitably furnished shall be arranged *pour le service médical*. By Article 228 it is enacted that the medical men chosen by the management shall be approved by the Prefecture of Police, save the medical men of the *théâtres nationaux*, who are appointed by the Ministry of Public Instruction and Fine Arts. Article 229 requires the management to notify to the *Préfecture de Police* the manner in which the *service médical* will be assured and regulated. The service by Article 230 must be organised in a manner so as to have a medical man always present in the establishment from the commencement of the performance until the end thereof, as well as at all rehearsals. To ensure the attendance of a qualified practitioner Article 231 declares that if *le médecin de service* is

[1] THE LANCET, Feb. 18th, 1911, p. 424.

[2] See Proceedings of the Royal Society of Medicine, November, 1910, and a paper now appearing in Professor Schäfer's Journal of Experimental Physiology.

prevented by any reason whatsoever from attending the performance, he shall immediately notify the management of the establishment that he will take the steps necessary to ensure the attendance of another medical man as a substitute. It is provided by Article 232 that every medical man who shall be shown to have been neglectful or unskilful in his service shall be struck off the list of doctors of the establishment, and his services replaced by the management in the conditions provided in Article 229. As to the furnishing of the surgery, Article 233 provides that a box of remedies shall be provided in the *cabinet du médecin*. This box of remedies shall contain things likely to meet the most urgent needs, and shall carry upon the inside of the cover the names of the medicaments and objects which are contained therein. *Le médecin de service* shall see that the instruments are always in a good state and that the medicaments have not deteriorated. He must transmit to the prefecture the result of his observations from time to time.

The police order from which the foregoing is taken supplements an ordinance of May 12th, 1852, and although that of August 10th, 1908, says little about the equipment of the medical man's room, yet we learn something of it from the discussions at the last Congrès International de Sauvetage which met at Brussels. The place for the reception of patients must have a bed, or a couch with pillows, chairs, a table, a wash-jug and basin, a water-bottle and glasses, napkins, a *couverture* of wool, some flannels, and a chandelier. The latter is explained from the fact that in 1852 there was no electric light. The medicaments, instruments, &c., are also scheduled. In effect, the ordinance stipulates that there shall be kept in the *cabinet du médecin* court plaster, amadou, lint, a dozen compresses, bandages, artery forceps, surgical needles, and splints and pads of different dimensions. For circuses and hippodromes there must be provided gouttières (wire-gauze splints) for the thigh, leg, arm, and forearm. The medicaments are, *inter alia*, distilled mint water, eau de Cologne, camphorated spirit, acetate of ammonia, sulphuric ether, packets of emetics of 5 centigrammes each, flour of mustard, and sugar.

The foregoing provisions apparently are satisfactory, but this is not exactly the case. Although Paris possesses a *conseil de salubrité* it seems, as was stated at the Brussels Congress, an anomaly that the duty of supervision should be vested in the prefecture of police. Article 233 of the last ordinance providing that the instruments, medicaments, &c., shall be in good state ends, "*Il devra Nous transmettre ses observations.*" The *Conseil de Salubrité* consists of doctor, pharmaciens, and others well qualified to have the supervision in general, yet it has not that power direct. It is the Prefect of Police who has to see that the theatre has a surgery, that it is properly furnished, that the box of medicaments does not want any of the medicaments that the *Conseil de Salubrité* considers of importance, and that its contents shall represent modern pharmaceutical knowledge and be in good condition.

The *Gaulois*, by no means satisfied with existing arrangements, goes so far as to say that if peradventure a person with a curious turn of mind went into the *cabinet du médecin* in some of the theatres and saw the box of medicaments, if it were not for its shape he would be pardoned for assuming that it was a case of Burgundy, for the dust upon it is sufficient to rejoice the heart of any butler. The writer in the *Gaulois*, generally well informed, proceeds: "A lady or gentleman in the audience may be taken ill, she suffering from the heat, and he, if he be waiting for a friend, from the crush. They are at once taken to the *cabinet du médecin*, and the doctor invariably orders the patient to the balcony. If the fresh air is inefficacious the doctor orders the patient's removal to the nearest pharmacy." The *Syndicat des Medecins des Théâtres*, consisting of 450 members, demand that the present state of things should be reformed, and in view of their mission and their responsibility they sent to the Brussels Congress Dr. Saqui. The doctor has already caused some commotion in managerial circles by the action he has taken, and at the congress he called for the strict observance of Articles 227 to 233 of the ordinance which I have discussed above. Dr. Saqui's resolution was carried unanimously. The *Gaulois* further points out that a place of entertainment may accommodate only 799 persons, and thus not come under M. Lepine's ordinance, and it calls for the extension of Article 227, so as to bring the smaller houses of entertainment within its operations.

It should be added there is no particular statutory obligation for theatres to have a medical practitioner in attendance during the performances, but the power of imposing such an obligation belongs to the municipal authority, represented in each commune by the mayor, except in Paris, where such power is vested in the Prefect of Police. The national theatres referred to in Article 228 of the ordinance are the Opéra, the Comédie Française, the Opéra Comique, and the Odéon. From the construction of Article 228 of the ordinance it seems clear that the management pay the practitioners for their services, but in regard to the State theatres the ordinance gives no indication as to whether the doctors are paid out of the public funds or by each individual theatre.

## LEEDS.

(FROM OUR OWN CORRESPONDENT.)

### *Leeds Sewage Works.*

IT may be remembered that some three years ago the West Riding Rivers Board took action against the Corporation of Leeds in connexion with the inadequate treatment of the sewage of the city, and that an order was made that "the defendants do forthwith commence and diligently proceed to carry out the necessary works to enable them to treat and deal with the whole of the dry-weather flow of liquid falling or flowing into the river Aire through the sewers and sewage disposal works of the defendants." Following on this the corporation has acquired a large area of land at Temple Newsom, and work has been going on actively. For many years there is no doubt the purification of the sewage, prior to its being turned into the river, has been most inadequate. For the present, however, Leeds is doing all it can to meet the demands of the rivers board. A complete sludge pressing plant has been put down to deal with the sludge after precipitation in the tanks, and now about 1000 tons are dealt with daily by being pressed into cakes which are used as manure. With the purchase of the land, however, there will follow the supplementary part of the scheme—namely, the provision of bacteria beds to which the effluent from the tanks after sedimentation will be pumped a distance of some two miles. The power required for the pumping will be provided from the electricity works of the corporation. However quickly the work goes on, and no time is to be lost in getting out specifications as soon as the consent of the corporation is obtained to the scheme, it will of necessity be at least two years before the new beds at Temple Newsom can be in actual use. It will also be necessary to construct two new large sewers, and in all it is understood that the scheme will involve an expenditure of £1,277,000. The ratepayers must console themselves with the knowledge that the expenditure is absolutely necessary, that the expense will be spread over ten years, and with the comforting reflection that Leeds may in the future have a river running through it which is not an offence to the eyes and to the nose.

### *The Leeds Association for the Prevention and Cure of Tuberculosis.*

The annual meeting of this association was held lately under the chairmanship of the Lord Mayor, Mr. W. Middlebrook, M.P., and was well attended. The hospital for acute cases is housed at Armley in the old family house of the Gotts, and a pleasing feature at the meeting was the announcement that Mr. Frank Gott, the representative in Leeds of that family, had as a coronation gift remitted the rent for the current year. The committee, in presenting its eleventh annual report, mentioned that the association now possesses 90 beds—35 at Gateforth and 55 at Armley—which is an increase of five on last year. At Gateforth 134 patients were treated as against 125 last year, while at Armley the numbers were 217 as against 207. In the out-patient department there has been a considerable increase of work, and this has involved the extension of the premises in Great George-street. During the past year the association has had the services of a visiting nurse, who has followed the patients to their homes and advised them in their efforts to carry out the advice of the medical officers of the institution. At Gateforth it is intended, when the increased accommodation for children is provided, to arrange for the presence of a skilled teacher who will carry on educational methods in the same way as is now being done in the open-air schools in

various parts of the country. The children in this department will be those with the mildest manifestations of tuberculosis and those who, though not consumptive, come from homes in which they are clearly exposed to infection. It was pointed out that the number of deaths from consumption in Leeds last year was 510 and from other forms of tuberculosis 241. The number of cases voluntarily notified last year was 1942, as against 934 for the previous year. It is clear that the association is doing excellent work and that it deserves every encouragement and support.

*Leeds Association for Nursing the Sick Poor.*

The annual meeting of this Leeds charity was held recently under the chairmanship of the Lord Mayor, when the record of the work of the past year was laid before the subscribers. This charity, supported entirely by voluntary subscriptions, is regarded as one of the most useful and possibly the least liable to abuse of all the charitable institutions of Leeds. The two special features by which it is characterised are that no case is undertaken by the association which is not under the care of a medical man, and that its main object is the nursing of the necessitous poor in their own homes. Patients are brought under the notice of the society in various ways; thus last year 2147 cases were recommended by private medical men and by club doctors, 315 by the officers of the Public Dispensary, 193 were patients who had been in the infirmary, 19 were former patients of the Hospital for Women and Children, while 371 were attended at the request of neighbours, 62 at that of clergymen and visitors, and 36 at that of inspectors, Poor-law medical men, and the Charity Organisation Society. There were on the books at the end of the year 283 patients, so that the total number of patients attended during the year 1910 was 3426, and on these the number of visits amounted to 87,806. An arrangement has been in operation with the Public Dispensary by which the attendance of a nurse has been secured for a certain number of hours daily, and this has been found of the utmost use. There are now four centres, and as soon as funds will allow other centres, for which there is a continual demand, will be organised. All who have worked, as your correspondent has done, with the assistance of these nurses will appreciate the excellence of the work which is being done, and bear testimony to the necessity of an extension of the scope of its activities. During the last year an experiment has been made in the provision of a special nurse who, on the payment of a small sum, will visit patients at their own homes, and in this way those whose circumstances do not permit of their securing the undivided services of a trained nurse, but who can afford a small sum, have privileges at their command which experience has shown that they are not slow to avail themselves of. It is hoped that this part of the work may increase, and care is being taken by a scrutiny of the applicants that abuse does not creep in on the part of those who could afford nurses from any of the private institutions of the city.

March 7th.

## WALES.

(FROM OUR OWN CORRESPONDENT.)

*Death of Dr. William Williams.*

THROUGH the death at Bournemouth on Feb. 16th of Dr. William Williams, medical officer of health of the county of Glamorgan, the county council has lost a loyal and efficient official and the public health service one of its most prominent members. He had been ailing for some months, and at the beginning of the year was given leave of absence for three months in the hope that a period of complete rest would restore him to health, but the anticipation unhappily was not fulfilled. Dr. Williams was born near Dolgelly in 1857 and was educated at the Dolgelly Grammar School, later proceeding to the Aberystwith College of the University of Wales and to Oxford, of which University he was M.A. and M.D. He also held the D.P.H. of Oxford. In 1892 he was appointed the first medical officer of health of Glamorgan and at once set about making a sanitary survey of the whole county, the record of which placed him at once in the front rank of sanitarians. He displayed great industry and much painstaking research in the collection of statistics relating to the incidence of puerperal fever and elaborated his original observations in the Milroy lectures in 1904. His most important work in later years was an elaborate report upon the water-supplies of the county of Glamorgan, which led the county council to decide to ask Parliament, though unsuccessfully, to sanction the formation of a water board for the county. The establishment of the Cardiff City and County Public Health Laboratory was largely due to his advocacy, and the good results which were anticipated from its formation have been more than justified. Dr. Williams was rarely, if ever, at cross purposes with the local authorities with whom he was brought officially in contact, and although of a somewhat retiring, almost shy, disposition he could hold his own in any of the controversies in which he was engaged, though his strength lay rather in the thoroughness with which he mastered his subject in the study than in his ability as a debater. The county council had come to regard him as a competent and safe adviser in the many problems with which it is beset in a rapidly growing industrial district, and the district councils accepted his recommendations, even though they sometimes acted upon them somewhat tardily. His death at the comparatively early age of 54 years is a source of great regret to all those with whom he was brought in contact, and the sincerest sympathy is felt with his widow and her three children in the loss which they have sustained.

*Swansea General and Eye Hospital.*

The Swansea Hospital was established in the year 1817, though the principal portion of the present building was not erected until the year 1869. Since that date extensions have been made, including a circular operating theatre, and there is now accommodation for 140 patients. During last year 1836 patients were treated in the wards and 9032 out-patients were dealt with. The finances of the institution appear to be in a satisfactory condition, for the expenditure of £9816 was more than met by the income to the extent of £800. It has been realised by the board of management for some time that the resources of the institution were being overtaxed, and a scheme has now been proposed by which 80 beds will be added to the hospital, a new dispensary will be erected, and a separate nurses' home provided. The scheme also includes a new waiting lobby, a covered way over the main entrance, additional bedrooms for the staff, rearrangement of the kitchen, and operating theatres for the eye hospital and for the out-patient department. The estimated cost of these alterations is about £30,000, towards which sum nearly one-fourth has already been promised.

March 7th.

## SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

*Royal Edinburgh Asylum.*

THE annual meeting of the Royal Edinburgh Asylum for the Insane was held on the afternoon of Feb. 27th in the City Chambers, Edinburgh, Lord Provost Brown presiding. The managers' report states that during the year the number of patients under treatment at Craig House reached its maximum, there being at one time 226 patients paying the higher rates of board. In the West House also the numbers had increased. The financial position of the asylum was satisfactory and the managers had embarked on the renovation of West House. The physician-superintendent, Dr. G. M. Robertson, read his report, which stated that the total number of patients on the register on Dec. 31st was 758, of whom 12 were absent on probation. There came under treatment during the year 947; cases discharged recovered numbered 70; discharged unrecovered 59; died 60. As causes of insanity alcoholic excess continued to hold the premier place. There seem to be indications that among men this cause was tending to diminish, but among women there was a decided increase. Influenza took the next place as an exciting cause. Political excitement had not furnished any cases of insanity during the year. Two cases were quoted in which cure was rapid after the administration of thyroid gland, and one of the insanity of exophthalmic goitre where cure resulted from treatment by the serum of a goat from which the thyroid

had been removed. In view of the interest aroused at present in the question of divorce for insanity the length of residence before cure becomes a matter of interest. Three patients recovered who had been respectively 6, 7, and 15 years in the asylum, and in another case insanity had lasted for over five years. These cases were all cases of melancholia, so that if ever incurable insanity of five years' duration be made a legal cause for divorce cases of true melancholia could hardly be included. The total number of deaths was 60, a proportion of 8 per cent. of the average number resident and the lowest death-rate for over 20 years. There were only five deaths due to consumption and in only one of these phthisis was not present on admission. The most important event of the year was the meeting of the Medico-Psychological Association at Craig House. At that meeting several papers were contributed by members of the Craig House staff. On the laboratory of the asylum the managers were spending £600 a year in salaries and working expenses, including therein a contribution towards the laboratory of the Scottish asylums of £175. The public might be assured that the gift of £100 or £150 towards the support of a research scholar would be money well expended at the present time. Salvarsan had been used in the treatment of general paralysis of the insane. In a good many cases there was no apparent benefit, but one case, one of the first to be treated, made almost at once the best apparent recovery of any case of undoubted general paralysis that Dr. Robertson had yet seen. He believed there was a defect in the links of the chain of reactions in the treatment of general paralysis by salvarsan. He was remedying this fault by injecting at the same time human serum from patients treated by salvarsan for another disease. The combined method gave more hope in combating the disease. With regard to the nursing, he had endeavoured to convert the asylum into a true hospital for the treatment of a special disease, administered on the lines of a general hospital, with female officials.

*Workmen's Compensation and Medical Examination.*

The Lord Justice Clerk in an important arbitration case under the Workmen's Compensation Act last week stated that where the employer intimated that he was prepared to pay compensation under the Act, and called upon the workman to submit himself to medical examination, any unnecessary delay on the part of the workman in submitting himself to examination would cut him off from compensation during the delay.

*Aberdeen Sick Children's Hospital: Annual Meeting.*

The annual meeting of the Royal Aberdeen Hospital for Sick Children was held in the Music Hall, Aberdeen, on March 1st. The financial statement showed that the ordinary income for the year 1910 came short of meeting the ordinary expenditure by £1192 10*s.* 10½*d.* Fortunately, however, during the year £2750 2*s.* 2*d.* were received in legacies, and £1150 2*s.* 2*d.* of this sum were transferred to the revenue account, thus reducing the deficit to £42 8*s.* 8½*d.* The sum of £600 was received during the year for the permanent endowment of a cot to be named "Stewart Wilson Cot, in memory of Betty Gow." As a result of the appeal for subscriptions for the new hospital fund £10,555 7*s.* 1½*d.* have already been received. The annual report showed that the number of in-patients for the year has been 954 and the number of out-patients 1892. The cost has been about 2*s.* 3*d.* per child per day. The report was unanimously adopted

*Carnegie Trust and Medical Inspection of Children.*

The report of the Carnegie Dunfermline Trustees on the medical inspection of school children which is undertaken by them has just been issued. When so much discussion has taken place regarding the various methods of carrying out this work, and so many different ways have been adopted by the numerous authorities for inspecting the children under their control, it is interesting to hear what measures have been taken by a burgh where in this matter expense is no object, and where an organisation is already in existence which should be able to give to the scheme its fullest development. The system in Dunfermline, which is carried out at the expense of the Trust, is much more elaborate and thorough than that adopted by any other town in Great Britain. In most other places public authorities could not afford to burden the rates with the expense which is borne by the trustees in making the system so efficient. The report, which is the work of Mr. John C. Bridge, is a volume of about 90 pages of charts and letterpress. At the outset it is stated that the inspection has been carried out on the following lines: Complete examination of the children at the four school periods, inspection of every child, and a complete examination of those children who have special defects, or who on inspection are deemed to require a special examination. In that way 4454 children have been examined and inspected during the year. Dealing with the school buildings, Mr. Bridge points out that two are not well situated from the health standpoint. Regarding nutrition, the report says that each year has shown that the children of Dunfermline fall below the general standard. Two factors contributing to the lack of proper nutrition are the want of sufficient sleep and the work as messengers done by school children after hours. Dr. Bridge expresses the opinion that one hour for dinner is too short, and adds that in 102 badly nourished children he found no trace of organic disease, their condition being due rather to want of proper feeding. In regard to cleanliness the standard is being raised, but he suggests that every house now built should have a bath, which he looks upon as being as necessary to the house as a kitchen.

*Another Gift to Dundee by Mr. J. K. Caird.*

Mr. J. K. Caird, LL.D., has purchased and given to the city of Dundee Spring Grove mansion house with an acre of garden to serve as a resting-place and reading-room for the aged and infirm; also £1000 to provide for repairs.

March 7th.

## IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

*Dinner of the Dublin University Biological Association.*

THE annual dinner of the Dublin University Biological Association was held last Saturday, some 80 covers being laid. Mr. W. I. de C. Wheeler, the President, was in the chair, and among the speakers were Sir Thomas Myles, Professor W. H. Thompson, Mr. W. Kennedy, Mr. E. H. Alton, Mr. Frazer, and Mr. Culverwell. Mr. C. Arthur K. Ball has been elected President for next session.

*A Compliment to Sir Charles Cameron.*

The members of his staff in the public health office of Dublin have presented to Sir Charles Cameron a replica in Irish walnut of the Speaker's chair in the Irish House of Commons.

*Death of Dr. Patrick O'Keeffe.*

Dr. Patrick O'Keeffe, who died last Sunday, was for many years senior medical officer to the Mountjoy Prison in Dublin. He began his career in the prison service in the old convict prison on Spike Island in Cork Harbour, where he had many of the Fenian prisoners of the '67 rising in his care. On the closing of that prison he was transferred to Mountjoy. Dr. O'Keeffe had an unerring memory for faces, so that he knew by sight an appreciable proportion of the habitual criminals in Ireland. Though a man of great humanity he never lapsed into sentimentality.

*Increased Accommodation at the Royal Hospital for Incurables.*

Plans for the new consumptive wing of this institution have been accepted and building is to commence shortly. The hospital now accommodates some 30 consumptives, but the new building is to afford beds for 100.

*Convalescent Home, Stillorgan.*

During the year 1241 patients were admitted to the Convalescent Home, Stillorgan, Co. Dublin, 933 to the free wing and 308 to the pay wing. Preference is given to those likely to be able to return to work after a short stay in the country, and particularly to patients from the Dublin hospitals. No fewer than 600 patients had to be refused admission for want of space, so the committee has decided to build an annexe capable of holding 12 beds.

*The Belfast Maternity Hospital.*

At the 117th annual meeting of this, one of the very oldest charities in the North of Ireland on Feb. 28th the medical report submitted showed that during 1910 there had been in all 1065 deliveries—viz., 546 in the

hospital and 519 in the extern district—with only four deaths, a mortality of only 0·37 per cent. In the gynæcological department there were 400 patients treated. Financially, the year was wound up with a balance in hand of £221 12*s.* 10*d.* The balance at the end of the previous year was £235 13*s.* 5*d.* An interesting feature of the meeting was the fact that one of the principal speakers was Mrs. Crozier, wife of Most Rev. Dr. J. B. Crozier, Archbishop of Armagh and Primate of All Ireland, whose great-great-grandfather, Dr. Bartholomew Mosse, founded the Rotunda Hospital in Dublin. At his own expense Dr. Mosse opened as a hospital a house in George's-lane, Dublin. This was the first maternity hospital established in the British dominions. Two years later application was made by some well-disposed persons in London to the directors of that hospital for plans, scheme, and regulations, and a year later a hospital was established in London. The hospital in St. George's-lane became too small, and eventually Dr. Mosse, in 1748, with his own restricted means, purchased the ground on which the present Rotunda stands. Dr. Mosse died in 1759, a comparatively young man, at the age of 47 years.

*Belfast Corporation Medical Officials' Salaries.*

The Belfast corporation decided on March 1st to advance the salary of the medical superintendent officer of health (Mr. H. W. Bailie) from £600 to £800, subject to the approval of the Local Government Board, and of the visiting physician to Purdysburn Fever Hospital (Dr. A. G. Robb) from £480 to £580.

*Ulster Medical Society.*

At the meeting of the Ulster Medical Society held on March 2nd in the Medical Institute, Belfast, Mr. A. B. Mitchell read a paper on 110 Consecutive Operations for Gastric or Duodenal Ulcer, done between September, 1908, and February, 1911, in all of which gastro-jejunostomy was performed, with or without some additional operation. The following of the paper was helped by the fact that the audience had in their hands a printed synopsis of the cases. In the discussion Dr. W. Calwell, Dr. J. Rusk, Mr. J. B. Moore, Mr. J. O'Doherty, and Mr. H. Stevenson took part.

*Irish Medical Association.*

The annual meeting of the Irish Medical Association is to be held in Cork, for the first time in 12 years, on June 13th. The meeting will be held in University College. The Lord Mayor and the High Sheriff will entertain the guests. Interesting excursions are being arranged.

*Royal National Hospital for Consumption for Ireland.*

This hospital reports year by year an increase of work. Its operation is confined as far as possible to early or incipient cases of the disease, where permanent alleviation or cure might be expected. In 1910 the number of cases treated was 440, of whom 86 were in hospital at the end of the year. The medical report classifies 59 as "very much improved," a term defined as meaning "apparent arrest of the disease, i.e., general health is completely restored; and there are either no physical signs in the lungs, or only those signs which are compatible with a completely healed lesion"; 85 patients are classed as "much improved," i.e., with "complete restoration of general health, physical signs still present but very much diminished"; 90 were "improved"; 60 cases remained "stationary"; 31 became "worse"; and 10 died. The average stay in hospital was about 11 weeks, the maximum being 46 weeks.

(FROM OUR OWN CORRESPONDENT.)

*Potatoes in the Dietary of Diabetic Patients.*

AT a meeting of the Société Médicale des Hôpitaux held on Feb. 17th M. Rathery said that it was an error to suppose that potatoes were an article of diet permissible to diabetic patients; he considered, on the contrary, that they ought never to be freely permitted in such cases. He quoted a number of clinical observations showing, on the one hand, that even such very small quantities of potatoes as 50 grammes might suffice to cause a reappearance of sugar in the urine, and, on the other hand, that diabetic patients did not by any means always assimilate the carbohydrates of potatoes more easily than those of other starchy foods; they sometimes even assimilated them less easily. Speaking generally, it might be said that in the majority of cases of diabetes potatoes were to be considered as an article of food similar to other dietetic substances rich in carbohydrates. In some cases, however, potatoes seemed to possess special properties of assimilation which might be either greater or less than those of other starchy foods. This was in fact a particular example of the law discovered by Bouchardat, according to which each diabetic patient had a personal coefficient for the quantitative and qualitative utilisation of carbohydrates.

*Hæmoglobinuric Bilious Fever in the Island of Réunion.*

Speaking on the subject of hæmoglobinuric fever at a meeting of the Société de Pathologie Exotique M. Ozoux said that an experience of 54 cases had led him to believe that no reliance could be placed on any of the orthodox remedies whether general or local; the jaundice, the pyrexia, and the hæmolysis usually resisted all forms of medication, and the disease came to an end without the clinical history supplying reasons for attributing the patient's recovery to any particular detail of the treatment. The best method seemed to M. Ozoux to be the administration of large doses of alkalies just as in yellow fever. Subcutaneous injection of fresh white of egg appeared to him to have a favourable effect on the hæmolysis and on the progress of the disease. The malarial origin of the disease and the influence of treatment by quinine were not proved. The mortality was 27 per cent. of the cases. Severe forms of the illness with hæmorrhage, uræmia, well-marked jaundice, and speedy death were frequent.

*Plague in Manchuria.*

At a meeting of the Academy of Medicine held on Feb. 21st M. Chantemesse made an interesting communication on the subject of the present severe epidemic of plague in Manchuria. He said that the marmots of Lake Baikal were very susceptible to the microbe of plague, and that the first persons attacked were six hunters in October, 1910, their symptoms consisting of spasmodic cough and profuse expectoration soon followed by death. The bacillus causing pneumonic plague, which was the prevailing type of the present epidemic, was allied to the bacillus which had been isolated in the bubonic form of the disease. Persons between 20 and 40 years of age were peculiarly liable to be attacked. The disease was spread principally by means of the railways on which germ-carriers were crowded together in the third- and fourth-class carriages. As the period of incubation was from eight to nine days, the distance to which germ-carriers were capable of conveying the infection might be imagined. The return of fine weather checked the progress of the disease, but did not arrest it. Prophylactic measures of vaccination had rendered great service in Manchuria.

*Bequests to Scientific Institutions in Paris.*

M. Loutreuil, a Frenchman of humble origin, who possessed little if any education at the time of leaving his native village, subsequently acquired an amount of scientific knowledge which he applied profitably in various industrial enterprises. Having made an immense fortune by his industry and ability during a 50 years' residence in Moscow, he resolved that the greater part of it should on his death be available for the benefit of science. He has accordingly bequeathed 100,000 francs to the Pasteur Institute, 1,000,000 francs for scientific research, 2,500,000 francs to the University of Paris, and 3,500,000 francs to the Academy of Sciences.

March 13th.

## BERLIN.

(FROM OUR OWN CORRESPONDENT.)

*The Hygienic Exhibition in Dresden.*

THE preparations for the great International Hygienic Exhibition to be held in Dresden are almost finished, and it is expected that this one will present a contrast to some other exhibitions by being ready on the day appointed for the opening in May. The principal roadway traversing the exhibition ground will be 40 metres broad and 700 metres long, and will extend in front of the pavilions officially assigned to the different nations represented. The pavilions

of Austria-Hungary, Russia, Japan, China, Switzerland, Brazil, Spain, and Mexico will be very fine, but the handsomest and best provided of all will be that of the French Republic, for which the French Parliament has allowed not less than 340,000 francs. It is much to be regretted that Great Britain will not be officially represented, although the committee, of which H.R.H. Prince Christian is patron, did everything that was possible in the hope of inducing the British Government to reconsider its decision. The German Empire, the individual German States, and the leading cities and great corporations of the Empire will, of course, do their best to make the exhibition a success. It will be divided into a scientific section and a general section. The scientific section will provide professional hygienists with opportunities of becoming acquainted with all the recent advances that have been made in the different branches of hygiene, subjects which are presumed to be well known to experts being excluded. The general section is intended for the public at large, and will give a complete view of the arrangements of hygienic institutions. The various subjects of exhibition, illustration, or discussion will be divided into 12 groups. The first group will include questions relative to air, light, soil, and water. The second group, which will deal with the hygiene of towns and dwelling-houses, will probably be one of the principal attractions of the exhibition; the methods of planning towns and cities, the hygienic features of public and private buildings, their ventilation, heating, lighting, and sanitary arrangements, and the multiplicity of contrivances essential to modern home comforts will be shown. A sub-group will include questions relative to cemeteries and crematoria. The third and fourth groups will be occupied with food, clothing, and physical culture. In the third group rational systems of feeding will be explained, specimens of food, both of good quality and spoiled, will be shown, and the influence of unwholesome food on health will be pointed out. An exhibition of artificial food preparations will be connected with that department. In the group which includes physical culture the advantage of cleanliness for the general health will be shown. In the fifth group will be shown the influence of work on the health of the individual, together with an outline of the arrangements made for protecting the health of those who are employed in factories and workshops. The sixth group will be devoted to infectious diseases, their prophylaxis and treatment; the seventh group to hospitals, sanatoriums, nursing, and first aid; and the eighth group to whatever concerns the health and well-being of children and young persons, including the care of infants and school children. The ninth group will have for its subject the hygiene of travel, illustrated by the arrangements made for the preservation of health on railways and on board ship; a great number of models will be shown in explanation of the methods and procedures described. The next two groups will take up military, naval, and tropical hygiene, whilst the twelfth and last will consider statistical questions. In addition to these 12 principal groups there will be an historical department, including models and documents concerning hygiene in former times; a special section on the hygiene of sport and athletics of every description will be connected with the exhibition, and an extensive athletic ground will be provided for the holding of great international competitions. There will also be a "sports laboratory," in which scientific observations may be made on athletes before, during, and after their various feats and exercises. From the above outline of the programme it may be seen that the International Hygienic Exhibition at Dresden promises to be one of the most remarkable events in the history of exhibitions.

### *Poisoning by Margarine.*

During the month of November, 1910, a considerable number of mysterious cases of poisoning occurred in various parts of Germany, some of them terminating fatally. It was, however, eventually ascertained that the cause of the poisoning was a certain kind of margarine made at a well-known margarine factory at Hamburg. Until Dec. 5th, 1910, there were 200 of these cases in Hamburg alone, together with a similar number in various other towns of Germany. It often happened that all the members of a family became ill after having eaten food prepared with this margarine. After the above date, however, only a few cases occurred because the sale of the preparation was stopped. Dr. Dunbar, chief medical officer to the hygienic institute of the State of Hamburg, has given in the *Deutsche Medizinische Wochenschrift* a description of the investigations that were made, as well as the results obtained. Margarine is very extensively used in Germany, the annual production being estimated at 100 millions of kilogrammes, having a value of 100 millions of marks = £5,000,000. It is manufactured by the chemical treatment of beef suet, to which some oil is added. A special Imperial law concerning the production of margarine stipulates, among other provisions, that it must contain at least 10 per cent. of sesame oil, and the sale of margarine is under strict control, great care being taken to prevent it from being mistaken for or sold as genuine butter. The boxes in which margarine is stocked in the shops have the word margarine printed on them. No undesirable results have been connected with the manufacture and sale of margarine until the cases of poisoning now under consideration. On inquiry at the margarine factory it was found that the poisonous product had been prepared with an oil which had been imported from India into England under the name of "cardamum oil," a specimen of which was supplied to the laboratory. It had a consistence similar to that of butter and a disagreeable aromatic smell. Administered to dogs 1·5 grammes of the refined oil produced vomiting within half an hour and contraction of the abdominal muscles, the dogs being to all appearance very ill. It was, therefore, obvious that the cardamum oil was the starting-point of the poisoning. To ascertain whether the poisoning was due to the oil itself or to some negligence in the process of refining, a quantity of the oil was refined in the laboratory itself, so that all the soluble toxic substances were removed. The result was that the action of the refined product on dogs was the same as that of the raw product. Dr. Dunbar tried to investigate the nature of the cardamum oil, but the inquiries which he made in that direction from chemists and commercial agents were completely without result, cardamum oil being totally unknown to them. The nature and the chemical constitution of the cardamum oil led Dr. Dunbar to suppose that it was identical with chaulmugra oil, especially because an examination of its optical properties showed that it produced a specific rotation of 50·4°. The high price of chaulmugra oil, which costs 9.50 marks per kilogramme, made it, however, unlikely that this oil was used in the manufacture of margarine. The cardamum oil, on the other hand, cost the factory only 21 marks (= £1 1*s.*) per 100 kilogrammes. Dr. Dunbar then made inquiries as to whether a similar low-priced fat could be obtained from some other euphorbiaceous plant, and he succeeded in ascertaining that the so-called "maratti" fat was identical in consistence, colour, smell, and chemical constitution with the cardamum oil, and that 2 grammes of "maratti" fat given to dogs produced vomiting after the same time as the same quantity of cardamum oil. He further succeeded in obtaining from the seed of hydnocarpus an oil having the same optical properties as "maratti" fat and cardamum oil, and producing in dogs the same symptoms. It thus became clear that the so-called cardamum oil used in the margarine factory was either "maratti" fat or a product derived from hydnocarpus. Three grammes of this margarine actually produced the same symptoms in dogs as 2 grammes of "maratti" fat. Margarine from other factories given to dogs was harmless. It is obvious from this incident that some control is needed over the use of the oils which are admixed with the real margarine.

March 6th.

## ITALY.

(FROM OUR OWN CORRESPONDENT.)

### *Mania Errabunda.*

THE press has been recording an unusual number of cases in which individuals, male and female, have left their homes and accustomed associations and, though traced to several points of their route, are still baffling the efforts of interested search parties. Descriptions of their personal appearance, of their dress, of every detail in fact which can lead to their discovery and reclamation, are accompanied by surmises as to the cause of their wayward obsession, "loss of memory" being the most common of these. In more than one case it has been made out that epilepsy has been not unknown in their family, while their demeanour for some time

before their abandonment of house and home has been suggestive of melancholia, incipient, if not confirmed. "Mania errabunda," according to a well-known medico-psychologist, is characteristic of the "dégeneré" in the social order, the "tramp," for instance, so familiar to rural life, illustrating in the individual what in racial or tribal grouping appears as the gipsy. Apart from the prominence lately given to three or more dramatic disappearances in the Italian press, and to at least as many in that of transalpine countries, the "wandering disease" is a subject of special interest to the profession in these days when neurasthenia, in its protean forms, is apt to culminate in psychoses hitherto but little encountered, associated as two of the Italian cases undoubtedly are with the artistic temperament and the emotional, not to say sensuous, life!

*"Physiognomic Diagnosis."*

Among the clinical teachers and consultants of the mid-Victorian era in Great Britain Professor Laycock of Edinburgh used to insist on the value of this as a guide to the nature, as well as the presence and prognosis, of disease. Set forth with much ingenuity and illustrative detail in his work on "Mind and Brain," his doctrine found acceptance abroad, particularly in Italy, where it numbered its most authoritative exponents in physicians who made a special study of infantile ailments. Physiognomic diagnosis indeed they maintained to be an indispensable resource in the case of inarticulate little subjects who could not explain or indicate their feelings, and the experience acquired in the children's ward served them in good stead even in the case of the adult or the elderly when oral utterance or explanation was difficult or defective. An interesting illustration of this was lately witnessed, according to report, in the case of Professor Mya, the leading Italian consultant in diseases of infancy, with which he combined a large experience in practice among the grown-up. He had himself been struggling against the infective malady prevalent in Florence, and though feeling ill continued to make his professional rounds. When sitting with his family at dinner he suddenly felt a sinking sensation. "Give me the hand-mirror" (*dammi lo specchio*), he said. A moment's glance seemed to satisfy him as to everything that facial expression could reveal. He recognised the first indications of the "facies Hippocratica" and had no longer the "will to live" any more than the power. He soon passed away knowing that his hour had come.

March 4th.

## UNITED STATES OF AMERICA.

(FROM OUR OWN CORRESPONDENTS.)

*Vital Statistics in New York City.*

THE New York records for 1910 show a decrease in the annual deaths of 13,066 persons, due to the increased sanitary control over disease. Tuberculosis claimed 1840 fewer victims, pneumonia 2203, and nephritis 1317. The lives of over 6000 infants were saved and of 6600 persons between the ages of 5 and 65 years; of those over 65 a little less than 500. A somewhat increased list of deaths from appendicitis is believed to show merely improved diagnosis, many such cases having been formerly attributed to acute indigestion. The Health Department has determined to prosecute physicians and midwives neglecting to register births; 35 cases have already been settled, mainly out of court, and some 50 are pending. During the month of January last there were registered 12,057 births, an increase over January, 1910, of 457. An amusing disclosure in connexion with births is the estimate of a telephone company that each birth causes on an average 300 telephone calls.

*Cocaine and its Derivatives and Morphine.*

The Health Department of New York has found it necessary to increase the stringency of its regulation of the sale of cocaine as well as of opium. Its latest ruling demands that:—

No cocaine or salts of cocaine, eucaine, stovaine, alpha or beta eucaine, either alone or in combination, or any substance under any other name giving a similar chemical test of cocaine, and no opium or official preparations of opium, and no morphine or salts of morphine, or the derivatives of either or any of them, shall be sold at retail by any person in the city of New York except upon the written prescription of a physician duly authorised to practise as such, or other person duly authorised by law to practise medicine and administer drugs or perform surgery with the use of instruments. Any such prescription shall not be refilled.

Exceptions are made in favour of official preparations of which the maximum dose is not greater than one-half grain of opium or its equivalent, and of liniments plainly marked as poisonous.

*Annual Report of the New York State Commission of Prisons.*

The annual report of the New York State Commission of Prisons has been recently issued. The report states that the prisons of New York State are greatly overcrowded. With a cell capacity for 1200, an average of 1850 men are confined in the old prison of Sing Sing on the Hudson. Some of these are housed in one of the chapels and in the loft of one of the workshops. Moreover, the cells themselves are small and insanitary.

*Milk Depôts in New York.*

New York is preparing to open 12 depôts for the free distribution of pure milk under the auspices of the Health Department. It is estimated that the cost will be about £8000 annually. They will dispense milk exclusively for the use of infants, thus avoiding conflict with two large private charities which distribute milk to all properly accredited applicants, and will pasteurise at a nominal charge all milk that is brought to them by those who prefer to avoid the appearance of mendicancy by purchasing their own supplies, but who cannot afford to install the apparatus for efficient sterilisation.

*An Attack on St. Luke's Hospital, New York.*

St. Luke's Hospital, a wealthy and influential institution, was recently the subject of a sensational attack by a man whose mother died in the institution; he brought charges of neglect, cruelty, favouritism, of forcing charity patients to do menial work, and others of similar tenour. The immense number of persons, quacks, followers of the "New Thought," "Christian Scientists," patent medicine manufacturers, and the like, who have grudges against the medical profession, quickly seized upon this incident to flood the papers with corroborative stories. As might have been expected, the subsequent investigation completely disproved the charges, but it furthermore brought out the fact that probably nowhere in the world is there such friendly coddling of patients as in St. Luke's. The staff is numerically very strong, which allows unusual time to be given to the needs, real or fancied, of each patient, and the nurses are recruited with discrimination. As an example of the generosity, if not the wisdom, of the institution it was learned that there is an unlimited supply of milk to be had night and day to which patients may help themselves. In the particular case concerning which the charges were brought it was found that the patient was irrational and that her hallucinations were quite misunderstood by the relatives.

*Dinner to Dr. Stephen Smith.*

Dr. Stephen Smith, the Nestor of the medical profession of New York, was entertained at dinner by the medical profession at the Plaza Hotel on the occasion of his eighty-eighth birthday on Feb. 18th. About two hundred medical men were present. Dr. Smith, in responding for himself, dealt chiefly with his reminiscences. He proposed a detailed State policy with regard to defectives. He would put criminals into training-schools. A large class of the insane—such as suffer from disturbance, not from disease, of the brain centres—he would place under skilled care. The others might be made useful by colonising large areas of farm lands with diversified industries. Dr. Smith has had a distinguished public career. He was one of the first heads of the New York Board of Health, and was also at the head of the New York department of charities.

*Death of Edward Gamaliel Janeway, M.D., LL.D.*

Dr. E. M. Janeway, one of the best known physicians of America, died at Summit, New Jersey, on Feb. 10th. He was born in August, 1841. Since 1864 he had practised continuously in New York city. He held many hospital appointments and had been professor of pathological anatomy, professor of medicine, and dean of the medical college of Bellevue Hospital. He was for many years Health Commissioner of New York city. Dr. Janeway was a quiet reserved man, not a prolific writer or speaker, but one who commanded the

entire confidence of the profession as a clinician, and was particularly noted for his skill in diagnosis.

*Investigations in Regard to Poliomyelitis.*

The Rochester, N.Y., Academy of Medicine has adopted resolutions asking the State Department of Health to make investigations into epidemic poliomyelitis, and petitioning the legislature to make an appropriation for the suppression of the disease. In the resolutions it is stated that "the attention of the State Commissioner of Health is called to the facts that poliomyelitis is prevalent in Canada along the Niagara frontier, and that there is constant intercourse during the summer between Canada and New York State, and that therefore interchange of information and an agreement as to quarantine regarding poliomyelitis between Ontario and New York State would be most desirable."[1]

*Philadelphia Census of Defective Children.*

A census of defective children in the schools of Philadelphia shows that there are therein 11,543 mentally defective pupils. Three kinds of deficiencies are mentioned in the report: (1) the "physically deficient," embracing the blind, deaf, speech defective, crippled, and epileptics; (2) the "mentally deficient," backward, feeble-minded, and imbecile; and (3) the "morally deficient," truants and incorrigibles. The first class, those who require instruction by special methods in small classes, number 1857 boys and 1063 girls; dull children who would be benefited by special instruction number 3362 boys and 3241 girls. Class 2. Feeble-minded children, who should really be in an institution, number 287 boys and 155 girls. Class 3. Truant, incorrigible, and vicious children of defective mentality, who should be segregated in special schools, 387 boys and 607 girls; truant, incorrigible, and vicious children of fair mentality, who should be segregated in special schools, 1082 boys and 40 girls.

*Bill Forbidding the Marriage of the Unfit.*

It is stated that a Bill has been introduced into the Pennsylvania Legislature forbidding the marriage of imbeciles, epileptics, and persons of unsound mind, of male paupers, of persons suffering from transmissible disease, or under the influence of alcohol or narcotic drugs. The definition of what is a transmissible disease may give some trouble.

*Singular Case of Aphasia.*

At the time of the tremendous dynamite explosion of Feb. 1st at Jersey City, immediately opposite New York, where the shock was plainly felt and thousands of square feet of window-glass were shattered, a young female stenographer was riding on a New York tram-car and sustained a shock which deprived her of speech and memory. She was found in this condition two days later, wandering about the streets of Poughkeepsie, 100 miles from New York, quite unable to give an account of herself. She was taken to the Hudson River State Hospital at Poughkeepsie and there hypnotised. On recovering consciousness the girl was able to recall everything up to the time of the shock, but nothing subsequent thereto.

*Straus Milk Plant in Washington.*

On Feb. 6th the United States Senate passed a Bill authorising the Secretary of the Treasury to accept the milk depôt and laboratory maintained until now in Washington by Mr. Nathan Straus. The depôt will be worked by the Public Health and Marine Hospital Service.

*Responsibility of a Municipality for Disease.*

The Supreme Court of Minnesota has recently decided that if the plaintiffs in a recent suit against the town of Mankato in that State can prove their plea, that deaths from typhoid fever were caused by the negligence of the town authorities, they may recover damages. This decision will probably be of wide-reaching importance. Hitherto such cases have been dismissed as "acts of God": now the owners of town water-supplies, municipal or private, will be stirred into unprecedented activity. There have been in various parts of the country disquieting instances of stifled inquiry into the causes of similar epidemics, particularly where private capital was involved.

*Reported Cure of Lock-jaw.*

An uncorroborated report comes from Minnesota of the cure of a case of tetanus by the intraspinal injection of a solution of Epsom salts. The case is said to have followed the loss of the patient's finger in a corn-shredder.

Feb. 28th.

[1] THE LANCET, March 4th, 1911, p. 626.

# NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

*The Malaria Committee of Bengal Presidency.*

A RESOLUTION by the Government of Bengal, sanctioning the appointment of a Provincial Malaria Committee, has been promulgated:

With a view to the systematic examination of problems connected with the prevalence of malaria, the Government of India have appointed a Central Scientific Committee, in consultation with whom the provincial organisations should in future work, and the recommendation on this point of the conference which assembled at Simla in October, 1909, to consider the whole subject of the prevention of malaria is quoted below:—"The Conference having learnt that the Government of India will appoint a Central Scientific Committee to direct and coördinate investigations, and that they will also appoint at the request of local governments, or on the recommendation of the Central Committee, officers to carry out investigations, recommends that a local organisation to work in consultation with this Central Committee be constituted in each province. The nature of each organisation should be settled by the local government and may take the form of the sanitary board. A conference consisting of the members of the Central Committee and a delegate from such local organisation should be held annually at such place as may be convenient for the purpose of reviewing the work done and preparing a programme of future work."

With the approval of the Government of India, and with the consent of the gentlemen named below, the Lieutenant-Governor in Council has decided to appoint a Provincial Malaria Committee in Bengal, which shall comprise the following members:—The Members of the Executive Council of the Government of Bengal in the Municipal (Medical) Department, President; the Secretary to the Local Government in the Public Works Department (Roads and Buildings Branch); the Secretary to the Local Government in the Public Works Department (Irrigation Branch); Major L. Rogers, I.M.S., M.D. Lond., F.R.C.P. Lond., F.R.C.S. Eng., Professor of Pathology, Medical College, Calcutta; Assistant Surgeon Upendra Nath Brahmachari, M.A., M.D., Ph.D. Calcutta, Teacher of Medicine, Campbell Medical School, Calcutta; Mr. Nil Ratan Sircar, M.A., M.D. Calcutta; and the Sanitary Commissioner Bengal, secretary. Questions relating to the prevention of malaria frequently present problems which have both a medical and an engineering aspect, and expert knowledge in either branch will be represented upon the committee thus constituted. The superior staff, which will be placed for the time being at the disposal of the committee, will comprise one deputy sanitary commissioner and one assistant surgeon. These officers will work under the direction of the committee, whose duty it will be, subject to the control of the local government, to supervise the direction and method of the inquiries to be undertaken, to scrutinise the results ascertained from time to time, and to assist with their advice all action taken to cope with the problem of malaria in Bengal. In other administrative matters connected with the subject, such as the distribution of quinine, the committee will be consulted by the local government as occasion may arise, while the sanitary board will be directed to seek their assistance in the consideration of the bearing upon the question of malaria prevention of any drainage projects which may be brought before them. A delegate from the provincial committee will attend annually at the Central Conference which the Government of India will convene. By the agency of the committee, the Lieutenant-Governor in Council trusts that the inquiries connected with this most important question will be conducted upon more systematic lines than has hitherto been the case, while as the result of their labours it is hoped that knowledge may in time be accumulated which will permit of the adoption of remedial measures calculated to effect a substantial diminution in the mortality and suffering at present caused by malaria in this province.

*The St John Ambulance Association.*

Colonel L. E. Anderson, R.A.M.C., Principal Medical Officer, Allahabad and Fyzabad Brigades, has kindly consented to act as moderator at the competitions for the Indian Railways and Indian Volunteers' challenge shields and the St. John Ambulance Brigade Challenge Cup, to be held on Feb. 24th and 25th in the Exhibition Buildings at Allahabad.

*Vital Statistics of the United Provinces for 1909.*

As was to be expected in a healthy year following a period in which malaria prevailed in severe epidemic form, both births and deaths decreased in number, the total births being

102,772, as against 108,360, and deaths 123,463, as against 148,447. The excess of deaths over births, which has been a marked feature of the United Provinces statistics for some years, continued, though it amounted to only 6·68 per 1000 of the population. Special reference is not generally made by commissioners in their divisional reviews to the infantile mortality in the towns. The Sanitary Commissioner states in his report that the provincial mortality in municipalities declined from 352·93 in the year 1908 to 281·68. Forty-two municipalities returned death-rates above the municipal average, Balrampur taking the lead with a rate of 463·51. Other conspicuous figures were Sitapur (457·83), Tilhar (410·17), Khairabad (393·60), and Farrukhabad (379·94).

*Appointment of Health Officer of the Bombay Municipality.*

The municipal corporation of Bombay has reappointed Dr. J. A. Turner to be executive health officer of the Bombay municipality for a further term of five years from Feb. 1st, 1911. The appointment was confirmed by the Governor of Bombay in Council, who endorsed the high praise that Dr. Turner's work has earned in all quarters, "noting with satisfaction the immense improvement in the sanitation of the city that has been effected during his term of office."

Feb. 11th.

## NOTES FROM CHINA.

(FROM OUR OWN CORRESPONDENT.)

*Plague in North China.*

SINCE my last report the epidemic has continued to rage up to Feb. 3rd, causing in Harbin alone an average of 200 deaths per diem. After this it dropped to 120, and has not risen during the past week, while every day sees a slight diminution. At the same time involution forms of B. pestis have been observed in the blood. It has been the rule rather than the exception to find the bacillus in the blood of pneumonic cases. After the epidemic had been almost stamped out at Tsitsihar (north-east of Harbin) it recurred among a regiment of Chinese soldiers sent there. Coming southward it has been found at every station on the line and in the neighbouring villages. At Changchun it has been particularly virulent. The official efforts were not strong enough to prevent the people concealing corpses in their houses with lamentable results, but the work is now better organised, being under a prefect who is also a medical man (Dr. Huang). At Mukden it still persists without diminution, and there is no town of any importance (except the port of Niuchwang) which has escaped. Roughly 80 per cent. of the cases are pneumonic, 15 per cent. septicæmic, and 5 per cent. intestinal. In the province of Shantung many villages have been affected, no doubt due to the returned labourers. A most curious feature has been the comparative freedom of the huge overcrowded cities of Peking, 750,000 inhabitants, and Tientsin, with over a million. In the former we have as yet had not more than 13 authentic cases, and in Tientsin there have been about 40. This freedom cannot be put down to sanitary measures, which are by no means ideal, though the Chinese authorities are gradually organising sanitary and preventive measures. Plague has been at the doors of these two cities thrice in the past ten years and has hitherto left them unharmed.

*Inoculation.*

A point of much importance that has been raised is the efficacy of Haffkine's vaccine prepared from bubonic strains as compared with that from local pneumonic bacilli. Hitherto all the vaccination has been done from bubonic strains, and notwithstanding the doubts expressed the evidence is all in favour of this course. Among the Russian staff the following deaths occurred: Two male doctors, not inoculated; one female doctor, partially inoculated, died two days after; one student, not inoculated; four ambulance men, partially inoculated; four sanitary men, not inoculated. Partial inoculation means, according to the Russian method, only half a dose the first time and a full dose the week later. One British doctor (Dr. A. F. Jackson) died 12 days after inoculation. He had become infected during the negative phase, the period of greatest infectivity, and was hard at work all the time among gangs of infected coolies. One Chinese (foreign-trained) doctor died after inoculation, but inquiry showed he had not had any reaction whatever, and it was thought probable from inquiries made that the operator had not shaken up the bottle. One Chinese (foreign-trained) medical student died seven days after inoculation. 1200 cubic centimetres of Yersin's serum prolonged the life of a Russian student to the seventh day of illness, and 140 cubic centimetres prolonged the life of a Russian sanitary man to the fourth day. With regard to the negative phase of inoculation, Dr. Haffkine (nephew of the Indian bacteriologist) confirmed the observations of Dr. J. G. Gibb, and has found at Harbin by clinical and laboratory evidence, as well as by Wassermann reaction, that it lasts five to seven days. He advises no one to come in contact with plague cases for ten days after inoculation. Out of 130 of the Russian sanitary staff of 390 who were successfully inoculated and passed the negative stage, though living all day among highly infectious cases, *not one* has developed plague.

*Clinical Symptoms*

Only one case of bubonic plague has been noted—a Russian sanitary man who had a submaxillary bubo which was followed by secondary pneumonia and death. All the other cases have been primary plague pneumonia, septicæmia, and an intestinal form. Often blood-stained sputum is the first symptom, the patient still declaring himself quite well. Examination generally shows rapid pulse and fever. Often a man can walk to hospital and be dead a few hours after arrival. In other cases feelings of illness with the typical weakness and giddiness come first, and are usually followed later, but by no means always, by bloody expectoration. Intestinal symptoms with abdominal pain and diarrhœa occur, but I have not as yet heard whether there is also blood infection. A man can often be diagnosed in the street as plague-stricken by his bloated face and suffused conjunctivæ. Often in the quarantine hospitals a "contact" has normal pulse and temperature one day with no sign of illness and is dead next day. On the other hand, quite a number of cases are set aside because of fever and fast pulse which turn out to be nothing. The doctors report that every day they feel more and more the difficulty of knowing whether a patient has plague or not, till he or she is within a day of death. Dr. Mesny, the French doctor who died, met his death while examining, uninoculated and unmasked, a pneumonia case who suddenly coughed in his face.

*Medical Staff.*

Dr. J. G. Gibb and Dr. Wu (Gnoh Lean Tuck) have been through the epidemic at Harbin from its early stage. I am indebted to the former for much of the clinical data given. Dr. W. H. Graham Aspland and Dr. J. M. Stenhouse have also been at Harbin doing heroic work amid very infectious surroundings. They have been assisted by Chinese doctors and students. At Changchun Dr. C. W. Young and Dr. G. P. Gordon are in charge; there are also Japanese doctors. Dr. Morikawa and his wife (Japanese) have both died here while on plague duty. At Mukden, Mr. D. Christie and Mr. A. R. Young, of the Scotch Presbyterian Mission, are directing plague work in conjunction with the Chinese authorities. The death of Dr. Jackson is much deplored. A trainload of 450 coolies southward bound was returned to Mukden as plague had broken out among them and deaths occurred. It was in the hard work involved in separating out actual cases and suspects from the other contacts that Dr. Jackson met his death. It remains to be said that all the medical reports made by foreign doctors in Manchuria testify to the way the Chinese officials are *now* backing up the measures advised and the active way they have organised and are carrying out antiplague work.

*Burial of the Dead.*

The greatest difficulty has been experienced in disposing of the dead. 150 grave-diggers took five days to dig a pit large enough to hold 100 coffins, the ground being frozen deeply. The dead, coffined and uncoffined, accumulated in huge stacks, but the local officials absolutely refused to cremate as advised by the foreign doctors. It was not until permission had at last been obtained from the Throne that the dead could be burned. Pits 15 feet deep and 25 feet wide were dug and fires of wood made in the centre of each, then the bodies were soaked in paraffin and poured in. Those in coffins were stacked, paraffin poured over them, and set alight. This was the procedure adopted in Harbin, and has been followed in other places where the dead have been too numerous to bury.

Feb. 12th

# Obituary.

## ARTHUR FRAME JACKSON, B.A., M.B., B.C. CANTAB., D.T.M. LIVERP.

Dr. A. F. Jackson, whose sad death in China from plague has already been chronicled in our columns, was born at Oxton 26 years ago and educated at Merchant Taylors' School, Crosby, Liverpool, and at the University of Cambridge. At the latter place he had a successful career both as a scholar and an athlete and afterwards studied medicine at Liverpool, becoming house surgeon and house physician at the Royal Infirmary there. At the end of September last he went to China as a medical missionary, taking up his appointment as a medical missionary on the staff of the large hospital at Mukden, Manchuria, where Mr. D. Christie carries on so much work on behalf of the Scotch Presbyterian Mission. "He has died," says our correspondent on the spot, "on the very threshold of a life's work which was full of promise. Dr. Jackson was an exceedingly fine young man. When the plague epidemic broke out at Mukden the city was divided into sections and an organised system of dealing with plague cases was instituted. Dr. Jackson at once volunteered to take charge of the seventh section, which included the railway and in which 80 per cent. of the total Mukden deaths have occurred. The inns here were heavily crowded with coolies on their way from the northern infected districts, and naturally the heaviest work fell to him. Early and late he was busy, and that in a temperature 20° below zero. Many a plague-stricken coolie received the strong support of Jackson's arm when being removed to hospital, and many died the easier for his having arranged a pillow for their heads. On Jan. 23rd he was in perfect health and high spirits, as by his own efforts he had established the isolation hospital. On the morning of the 24th he seemed drowsy and was persuaded to return to bed, which he did with reluctance. Mr. Christie was called and soon detected the early symptoms of plague. Along with Mr. A. R. Young (Mr. Christie's chief assistant) injections of Yersin's serum were given and everything that medical science could do was done for him, but on Jan. 25th he died. His short period of work in China was full of usefulness, and the speech made at his burial service by the able Viceroy Hsi Liang, which is appended, has made a great impression not only among foreign residents here but also among the Chinese officials."

The following is a translation of the speech delivered by Viceroy Hsi Liang at Dr. Jackson's memorial service on Feb. 1st:—

We have shown ourselves unworthy of the trust laid upon us by our Emperor; we have allowed a dire pestilence to overrun the sacred capital.

His Majesty the King of Great Britain shows sympathy with every country when calamity overtakes them; his subject, Dr. Jackson, moved by his Sovereign's spirit and with the heart of Christ, who died to save the world, responded nobly when we asked him to help our country in its time of need.

He went forth to help us in our fight; daily where the pest lay thickest, midst the groans of the dying he struggled to cure the stricken, to find medicine to stay the evil.

Worn by his efforts, the pest seized upon him and took him from us, long ere his time. Our sorrow is beyond all measure, our grief too deep for words.

Dr. Jackson was a young man of high education and great natural ability. He came to Manchuria with the intention of spreading medical knowledge, and thus conveying untold blessings upon the Eastern peoples. In pursuit of his ideal he was cut down. The Presbyterian Mission have lost a recruit of great promise, the Chinese Government a man who gave his life in his desire to help them.

Oh, spirit of Dr. Jackson, we pray you intercede for the 20,000,000 people in Manchuria, and ask the Lord of Heaven to take away this pest so we may once more lay our heads in peace upon our pillows.

In life you were brave, now you are a spirit. Noble spirit, who sacrificed your life for us, help us still, and look down in kindness upon us all.

THE report of the committee of management of the City of London and East London Dispensary, which supplies medical and surgical advice and medicines to the necessitous poor gratuitously, and to other poor persons for small weekly payments, states that the number of attendances during the year was 111,262, of which 5073 were free, showing an increase of 2135 over those of the year 1909. The receipts from the subscribing members were £2654 14*s.* 6*d.*, being £53 13*s.* 6*d.* in excess of those for the previous year, and the donations and subscriptions amounted to £100 19*s.*

# Medical News.

FOREIGN UNIVERSITY INTELLIGENCE.—*Cagliari:* Dr. Francesco Putzu has been recognised as *privat-docent* of External Pathology.—*Erlangen:* The Chair of Laryngology having been declined by the Giessen Professor, has been offered to Professor Lange of Greifswald. *Genoa:* Dr. Enzo Bizzozero has been recognised as *privat-docent* of Dermatology.—*Giessen:* As Professor von Eicken has decided to remain at Giessen instead of accepting the offer of a chair at Erlangen, the Hessian Government has decided to build a new clinic for throat and ear diseases.—*Göttingen:* Dr. Walter Fischer has been recognised as *privat-docent* of Pathological Anatomy.—*Greifswald:* The title of Professor has been conferred upon Dr. Guido Fischer, the *docent* of dentistry, who is migrating to Marburg. Dr. Friedrich Hohmeier has been recognised as *privat-docent* of Surgery.—*Kiel:* Dr. F. Klein, *privat-docent* of physiological chemistry, has been appointed Extraordinary Professor.—*Königsberg:* Dr. M. Kirschner has been recognised as *privat-docent* of Surgery, and Dr. K. H. Sattler as *privat-docent* of Ophthalmology.—*Modena:* Dr. Giuseppe Frattin of Padua has been recognised as *privat-docent* of External Pathology.—*Naples:* Dr. Francesco Franceschi has been recognised as *privat-docent* of Neurology and Psychiatry, and Dr. Giuseppe Procopio as *privat-docent* of Midwifery and Gynæcology.—*Padua:* Dr. Italo Simon of Parma has been recognised as *privat-docent* of Materia Medica and Experimental Pharmacology.—*Palermo:* Dr. Emerico Luna has been recognised as *privat-docent* of Anatomy.—*Parma:* Dr. Giacomo Zaccarini has been recognised as *privat-docent* of External Pathology.—*Pavia:* Dr. Livio Losio has been recognised as *privat-docent* of Operative Medicine.—*Philadelphia (Jefferson Medical College):* Dr. John Funke has been appointed Lecturer on Diseases of the Heart.—*Pisa:* Dr. Luigi De Gaetani of Messina has been recognised as *privat-docent* of Anatomy.—*Rome:* Dr. Italo Giuseppe Roses has been recognised as *privat-docent* of Internal Pathology, Dr. Francesco Chidichino as *privat-docent* of Midwifery and Gynæcology, Dr. Domenico Tanturi as *privat-docent* of Otology and Laryngology, and Dr. Cesare Serono as *privat-docent* of Medical Chemistry.—*St. Louis (Washington University):* Dr. David L. Edsall, of the University of Pennsylvania, has been appointed Professor of Preventive Medicine.—*St. Petersburg (Women's Medical Institute):* Dr. V. Rokitski has been recognised as *privat-docent* of Surgery.—*Strasburg:* Dr. Uhlenhuth of Berlin has been appointed Director of the Hygienic Institute.—*Turin:* Dr. Gaetano Samperi has been recognised as *privat-docent* of Ophthalmology, and Dr. Alessandro Vaccari as *privat-docent* of Midwifery and Gynæcology.

LITERARY INTELLIGENCE. — The Cambridge University Press has made arrangements for the appearance of a comprehensive English botany, or "Flora," by Dr. C. E. Moss, the curator of the Cambridge University Herbarium, the author receiving assistance from specialists in several departments of the work. The descriptions of the plants will be new, and taken from living specimens, although older descriptions, as well as herbarium specimens, will be consulted. Engler's system of classification will, generally speaking, be followed; and the first volume to appear will deal with the earlier Dicotyledonous families from the Salicaceæ to the Chenopodiaceæ. The work will be illustrated by pen-and-ink drawings by Mr. E. W. Hunnybun, made from living specimens, each plant being drawn natural size; and in the case of critical species and varieties the name of each specimen is vouched for by some competent authority. In addition to these drawings each volume will contain numerous photographs of plants in their natural habitats, and maps showing the distribution of the more interesting genera and species. The work will probably be completed in ten volumes.—Messrs. Longmans, Green, and Co. are about to publish the Life and Letters of Sir John Hall, M.D., K.C.B., the principal medical officer of the Crimea during the great campaign. This is a biography of a distinguished Englishman written by a well-known Hindu, Mr. S. M. Mitra. Rear-Admiral Sir Massie Blomfield, who served

throughout the Crimean campaign, has written an introduction. The book deals with Sir John Hall's career in Flanders, the West Indies, Spain, South Africa (including the Kaffir War of 1852), India, and the Crimean campaign. It will contain several illustrations, including one of the wounded at Waterloo, Dr. Hall being then a hospital assistant.

UNIVERSITY OF OXFORD.—Mr. Edward Treacher Collins, F.R.C.S., has been appointed an examiner for the Diploma in Ophthalmology for 1911 and 1912.—Mr. R. C. Wingfield has obtained the degree of B.M., B.Ch.—The Board of Faculty of Medicine gives notice that in accordance with the provisions of the statute approved by Convocation on Nov. 15th, 1910, it has added the following clause to its regulations :—

> No candidate, unless he be already a registered medical practitioner, shall be admitted to the examination in medicine, surgery, and midwifery until a period of at least 22 months shall have elapsed from the date of his passing the first examination for those degrees.

THE Nottingham and Notts Association for the Prevention of Consumption has organised a Tuberculosis Exhibition to be held in the Mechanics' Hall, Nottingham, which is to be opened on Monday, March 13th, by the Duke of Devonshire. The exhibits of the National Association for the Prevention of Consumption and the Women's National Health Association of Ireland, together with many items of local interest, will be on view. Dr. Philip Boobbyer, Dr. Marcus S. Paterson, Dr. R. W. Philip, Dr. J. D. Slight, Dr. Jane Walker, Dr. Ralph Williams, and Professor G. Sims Woodhead have consented to give lectures in connexion with the exhibition during the week.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL.—The annual meeting of governors and subscribers of Queen Charlotte's Hospital was held on Feb. 28th, Mr. Frederick W. Hunt (Vice-President) being in the chair. During the year 1775 women had been admitted to the wards of the hospital, and 2449 others had been attended and nursed in their own homes. The report referred to the very low rate of mortality—namely, 3·3 per 1000 in the case of the in-patients and 0·4 per 1000 in the case of the out-patients. A grant of £1500 had been received from King Edward's Hospital Fund, £500 of which were towards improvements recently carried out, including the installation of electric light and electric sterilisers. The chairman stated that the income had showed some improvement over recent years, and the committee had been able to clear off the deficit of £3287 incurred during the years 1907, 1908, and 1909. There was, however, still a debt of £2130 on the nurses' home which the committee was anxious to pay off. The work done by the hospital in training medical students, midwives, and monthly nurses steadily increased, and the applications received at the hospital for maternity nurses for private cases showed that the establishment of the private nursing staff was greatly appreciated by the public and the medical profession.

SEVENTH INTERNATIONAL CONGRESS AGAINST TUBERCULOSIS, ROME.—As we announced in THE LANCET of Sept. 10th last (p. 844) this congress will be held in Rome from Sept. 24th to 30th, 1911. The president of the congress is Professor Guido Baccelli and the secretary-general Professor Vittorio Ascoli, whose address is 36, Via in Lucina, Rome. The last International Congress against] Tuberculosis, at Washington in 1908, chose Rome as the meeting-place of the Seventh Congress. The work of the congress will be divided into three main sections as follows: (*a*) Etiology and Epidemiology of Tuberculosis; (*b*) Pathology and Therapeutics (Medical and Surgical) of Tuberculosis; (*c*) Social Defence against Tuberculosis. Those who wish to take part in the congress are requested to fill up a form which can be obtained on application, stating therein the section for which they desire to enter their name and enclosing the form together with a visiting card and a fee of 25 francs for a member's ticket. Members' relatives can obtain tickets at 10 francs each. The payment is requested to be made by international postal order payable to the treasurer of the Congress, and addressed to the secretary's office. The members' tickets give their holders the right to obtain reductions in railway fares and admission to various social gatherings. The Congress will be opened in the large amphitheatre of the Augusteo in the presence of the King and Queen of Italy. The meetings of the Congress will be held in the Castle of S. Angelo.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—Sir Arthur Chance has been appointed as the representative of the College on the General Medical Council.

A DINNER of the Irish Medical Schools and Graduates' Association will be held on Thursday, next, March 16th, at 7.15 P.M., in the Indian Room, Hotel Cecil, Strand, W.C. The Duke of Abercorn, Sir Thomas Barlow, and Sir Henry Morris will be present.

LONDON OPHTHALMOLOGICAL EXHIBITION.—The committee of the London Ophthalmological Exhibition and Conference invite attendance at an optical and electromedical exhibition held to-day and to-morrow (Friday and Saturday) at the rooms of the Medical Society, 11, Chandos-street, Cavendish-square, W. The exhibition will be open from noon to 10 P.M. each day.

DONATIONS AND BEQUESTS.—Mr. Richard Murray of Harrogate has given 150 acres of land, £10,000 in cash, and £20,000 in investments for the building and endowment of a hospital in memory of King Edward VII.—The late Mrs. Mary Ann Fitzherbert Fraser bequeathed £5000 to the Seamen's Hospital Society.—Mrs. Jackson, mother of Dr. A. F. Jackson, who died from plague at Mukden on Jan. 26th, has presented to the Medical College of that city the £1000 received from the Chinese Viceroy.—Lord Stanmore has given £500 towards an endowment fund for the Royal Victoria Nursing Home at Ascot.—Mr. W. Graham Vivian, J.P., Clyne Castle, has subscribed £1000 to the Swansea Hospital extension scheme.—The late Rev. H. E. H. Mairis of Bristol has left, among other charitable bequests, £1000 each to the Cancer Hospital, Brompton, the Deaf and Dumb Asylum, Cannon-street, and the Hospital for Sick Children, Great Ormond-street; £500 each to the Home for Blind Children, Kilburn Priory, the Royal Hospital for Incurables, and the Brompton Hospital for Consumption; £100 each to the Throat Hospital, Golden-square, London, the Bristol General Hospital, and the Bristol Royal Infirmary.

# Parliamentary Intelligence.

## NOTES ON CURRENT TOPICS.

*The Nurses' Registration Bill.*

THE text of the Nurses' Registration Bill which was recently introduced into the House of Commons by Mr. MUNRO FERGUSON, has been issued. Its proposals are in the main similar to those which found a place in last year's Bill (*vide* THE LANCET, vol. i., 1910, pp. 831-832). It entrusts the duty of compiling a register for which only duly qualified nurses are eligible, to a General Nursing Council, and it gives power to the council to remove from the Register persons found guilty of conduct disgraceful in a professional respect.

In the first place the Bill provides for setting up "the General Council for the Registration of Nurses in the United Kingdom." The composition of this Council has given considerable trouble to the framers of the Bill in past sessions. The proposed clause for dealing with this matter is similar to that of last year's Bill, but as there is no register of nurses in existence it would be impossible to elect direct representatives of registered nurses to the first council, and the Bill provides that on the first constitution of the council in place of the direct representatives of registered nurses there should be 14 persons appointed for the most part by various associations interested in nursing. When the Register is sufficiently advanced to admit of an election of direct representatives, the provisional council will give way to the fully constituted one. The term of office is to be five years.

A correct register of nurses, to be called "the Nurses Register," is to be kept in accordance with the provisions of the Bill and the orders and regulations of the Council. Clause 10 lays down the duties and powers of the Council in language similar to that of the previous Bill.

Three clauses lay down the conditions under which admittance may be gained to the register (1) by existing nurses; (2) by nurses who shall become qualified at a future date; and (3) by nurses trained in the colonies. The conditions also correspond to those of the previous Bill.

Reciprocal recognition of the qualifications of colonial-trained nurses is given by Clause 14.

When the Nursing Council refuses to recognise any hospital or institution as an approved training school for nurses, an appeal lies to the Privy Council, whose decision shall be binding on the Nursing Council.

By Clause 15 the Nurses Register shall comprise—(1) a general register of women nurses containing the names of women who have been registered; (2) a supplementary register of male nurses; and (3) a supplementary register of asylum-trained nurses to be called the Mental Nurses Register. Clause 18 provides that unqualified persons holding themselves out as registered nurses, registered male nurses, or registered mental nurses are liable to prosecution, and on summary conviction to a fine not exceeding £10. There are also penalties for obtaining a certificate by false representation. It is noticeable that an appeal from the decision of the General Nursing Council lies to the High Court (or to the Court of Session in Scotland) in cases where the name of a nurse has been removed from the Register.

By Clause 23 it is laid down that nothing contained in the Bill shall be considered as conferring any authority to practise medicine or to undertake the treatment or cure of disease. This provision has been inserted in the Bill at the request of members of the medical profession, although the framers of the Bill contended that it had no more effect than merely to declare the existing law.

*Industrial Poisoning.*

The preliminary tables of cases of industrial poisoning, fatal and non-fatal accidents, and dangerous occurrences in factories, workshops, &c., during the year 1910 have been published. The figures, however, are subject to correction. The total number of cases of industrial poisoning for the year was 573, of which 48 had a fatal termination. This compares with 625 cases and 42 deaths in 1909. The figures for 1910 are made up as follows:—Lead poisoning, 505 (with 38 deaths); mercury poisoning, 10 (with 1 death); arsenic poisoning, 7; and anthrax 51 (with 9 deaths). No cases of phosphorus poisoning were reported in 1910.

*University of Wales Bill.*

Sir DAVID BRYNMOR JONES on Thursday, March 2nd, introduced a Bill in the House of Commons "to define and enlarge the rights of graduates in medicine of the University of Wales." The Bill, which is supported by Lord NINIAN CRICHTON-STUART, Sir HERBERT ROBERTS, and Mr. ORMSBY-GORE, was read a first time.

## HOUSE OF COMMONS.

WEDNESDAY, MARCH 1ST.

*The Dangers of Flannelette.*

Mr. THEODORE TAYLOR asked the Secretary of State for the Home Department whether he was aware that in England and Wales 700 persons were annually burnt to death owing to flannelette garments catching fire; that during the months of November, December, and January last over 400 persons were burnt to death in consequence of their clothing catching fire; and that it was possible to treat flannelette in such a way as to render it permanently resistant to flame; and whether the Government contemplated the introduction of any legislation as a result of the evidence presented to the coroners' committee on this question.—Mr. CHURCHILL replied: The figures referred to by my honourable friend have not been brought to my notice and I do not know on what authority they are given. From the Registrar-General's last returns, which are based on coroners' certificates, it would appear that in 1909 the number of deaths from burning clothes was 689, but only in 73 cases is it stated that the clothing was made of flannelette. As regards the possibility of treating flannelette in such a way as to render it permanently resistant to flame, I must refer my honourable friend to the findings of the Coroners' Committee on the point. I fear there is no prospect of legislation on this question during the present session.

*Phosphates in Flour.*

Mr. LONSDALE asked the Parliamentary Secretary to the Board of Agriculture whether the attention of the department had been called to the fact that, in violation of the Merchandise Marks Act, some millers, who were known to the Local Government Board, resorted to the practice of adding phosphates to the flour milled; and whether it was the intention of the department to put in force the powers which it possessed to check this practice.—Sir EDWARD STRACHEY replied: The Board is in communication with the Local Government Board on this subject. It would be very willing to consider the possibility of instituting proceedings under the Merchandise Marks Act in any specific case which may be brought to its notice.

Mr. LONSDALE also asked the President of the Local Government Board whether he was yet in a position to state the results of the investigation which he had instituted into the practice of adulterating flour by the addition of phosphates, whether made from the bones of animals or lime and sulphuric acid, and the nature of the action which he contemplated to put a stop to this practice.—Mr. BURNS answered: I am expecting to receive at an early date the report of my officer who has been investigating the question of flour. When I have received it the whole question will have my careful consideration.

Mr. LONSDALE: Is the right honourable gentleman aware that I asked a similar question in this House about five months ago, and the reply he gave me on that occasion was in similar terms?—Mr. BURNS: It is perfectly true that when the honourable gentleman asked that question I deemed it advisable to extend the scope of the inquiry. I am glad to say that the whole report will probably be out next month.

Mr. LONSDALE: In the meantime may I assume that people are to go on being poisoned?—Mr. BURNS: No. The honourable Member must not assume that. The interest that is being taken in this question is due to the fact that the press ascertained I had appointed two officers to make this investigation eight months ago.

Mr. LONSDALE: Perhaps the right honourable gentleman will not object to my putting a further question to him in a fortnight.—Mr. BURNS: I think long before a fortnight the report will be laid on the table of the House.

THURSDAY, MARCH 2ND.

*Small-pox in London.*

Mr. LANSBURY asked the President of the Local Government Board, with reference to the outbreak of small-pox in London, whether he would state how many cases had been notified; how many cases had been removed to the Joyce Green Hospital; how many of the cases were employed at the Mile End Infirmary and in what capacity; and what was the age and vaccinal condition of each patient.—Mr. BURNS (by written answer) replied: Since the beginning of the present outbreak 47 persons have been admitted at South Wharf; three of these have been found not to be suffering from small-pox; 43 cases, notified as small-pox, have been sent to Joyce Green; one case remains at the Wharf. Seven of the cases notified were persons employed at the Mile End Infirmary, five as nurses and two as scrubbers. I cannot give the age and vaccinal condition of each patient, as these particulars have not yet been verified; but it is stated that of the 44 patients six are 5 years of age or under, and of these three have not been vaccinated, three were vaccinated in infancy, two have been revaccinated since the onset of the disease. Seven are between 5 and 15 years of age, of whom one has not been vaccinated, five were vaccinated in infancy, one case is doubtful; four cases have been vaccinated since the onset of the disease. Fifteen are between 15 and 30, of whom two have not been vaccinated, 12 were vaccinated in infancy, one is doubtful; eight of these have been revaccinated since the onset of the disease. Sixteen are cases of persons over 30, of whom 14 were vaccinated in infancy; two cases are doubtful; 10 cases have been vaccinated since the onset of the disease. There has been one death, a case of an unvaccinated child of 3 years.

*The Teeth of School Children.*

Mr. CHARLES BATHURST asked the Parliamentary Secretary to the Board of Education whether, as the result of the statement contained in the annual report for 1909 of the chief medical officer of the Board that 20 to 40 per cent. of the 6,000,000 children in the public elementary schools of England and Wales suffered from extensive and injurious decay of the teeth, and in view of the opinion of the medical officers that such condition was largely traceable to the consumption of bread from which the germ and the skins of the grain had been mechanically extracted to ensure whiteness, and of the general ignorance as to food values and the preparation of food for human consumption, any steps were being taken by the Board, by the preparation of a special syllabus of domestic economy instruction or otherwise, to minimise the magnitude of youthful physical degeneracy disclosed by the above report.—Mr. TREVELYAN replied: The Board's medical officers have expressed no opinion as to the relation between the consumption of bread of any particular character and the decay of the teeth.

MONDAY, MARCH 6TH.

*An Alleged Outbreak of Trachoma.*

Mr. RAINY asked the Secretary of State for the Home Department whether his attention had been called to the outbreak of trachoma a the Dover Gordon Boys' Home; whether he was aware that boys were returned to the home by the emigration authorities as not passable by them as emigrants owing to their suffering from this disease; whether he was aware that attempts were made to draft boys under observation into the navy and army unknown to the doctors in charge of the cases; whether he was aware that the segregation ordered by the oculist first called in was stopped and that since that date a new outbreak had occurred; whether he was aware that it was now proposed to dismiss all the boys to their homes without guarantee that they were free from infection of this most contagious disease; and what steps he proposed to take to deal with this situation.—Mr. CHURCHILL replied: I had not heard of this matter until my honourable friend's question appeared on the paper on Saturday. The school is not under the inspection by my department, but I will at once see that inquiry is made. I may say that the Home is not connected with the National Memorial Gordon Boys' Home at Woking.

*School Children and Vaccination.*

Mr. RAMSAY MACDONALD asked the President of the Board of Education whether any inspection of school children attending London County Council schools to ascertain the vaccinal condition of such children had taken, or would take, place; whether it was proposed to exclude unvaccinated children from such schools; whether such action was in accordance with the regulations of the Board of Education, and what action he proposed to take in the matter.—Mr. RUNCIMAN replied: I have no definite information as to any action which the London County Council have taken or are about to take to ascertain whether children in public elementary schools have or have not been vaccinated. I have several times expressed my view on the matter and may refer the honourable Member to an answer which I gave in this House on Oct. 14th, 1908, when I said that "I strongly deprecate any attempt on the part of local authorities to use the machinery of medical inspection for the purpose of enforcing vaccination. Such action is likely to discredit medical inspection in the eyes of many parents who would otherwise be glad to take advantage of it." With regard to the second part of the question, I have no information as to any proposal to exclude unvaccinated children from the schools. In the circumstances the third and fourth questions do not arise.

Viscount HELMSLEY: Seeing that recently there has been an outbreak of small-pox will not the right honourable gentleman reconsider his advice to the local education authorities in reference to medical inspection, seeing that the advice may render parents unwilling to go in for vaccination for their children.—Mr. RUNCIMAN: No, sir, I have no intention whatever of altering my advice. The case of epidemics is fully dealt with in the code.

*The Outbreak of Small-pox.*

Dr. HILLIER asked the President of the Local Government Board how many cases of small-pox there were at present reported in London; and whether he had requested medical officers of health to use every legitimate means to induce all those who had been brought in contact with these cases to be vaccinated.—Mr. BURNS answered: Up to last night the number of cases of small-pox which had been reported was 47. A medical inspector of the Board has conferred with the medical officers of health and with the officers of the guardians in regard to the steps to be taken for dealing with the outbreak.

Dr. HILLIER: Is the medical inspector urging the vaccination of contacts?—Mr. BURNS: The medical inspector of the Board and the local

medical inspectors are, I am glad to say, doing everything that reasonably can be expected in battling with this outbreak.

Viscount HELMSLEY: Will the right honourable gentleman give definite instructions to the medical officers to urge vaccination wherever they can?—Mr. BURNS: I shall deem it my duty to leave it to the medical officer of the Board and to the local medical officers of health.

Dr. HILLIER also asked the right honourable gentlemen to state how many sanitary authorities in the country were proposing the expenditure of ratepayers' money to provide additional hospital accommodation for small-pox on the alleged ground of the danger to the community consequent on the slackening of compulsory vaccination.—Mr. BURNS replied: I have no information that any sanitary authorities are proposing to provide additional hospital accommodation on the ground mentioned.

Dr. HILLIER further asked the right honourable gentleman what was the proportion during last year, relatively to the children born, of those children who were exempted from vaccination under exemption certificates.—Mr. BURNS replied: I am not at present able to supply figures for the whole year. During the first half of the year, however, 456,533 births were registered and 110,851 exemption certificates were received.

TUESDAY, MARCH 7TH.

*The Nutritive Value of Rice.*

Mr. CHARLES BATHURST asked the President of the Local Government Board whether the Board was taking any steps, through the medium of the medical officers of health of the local authorities or otherwise, to demonstrate the high nutritive value, especially to young children, of unpolished as compared with polished rice, and the unwholesome character of the latter when, as often happened, a high percentage of the talc, steatite, or gypsum employed in the polishing process was left in the finished product as sold in this country. The honourable gentleman also asked whether, in consequence of Dr. J. M. Hamill's report to the Board in 1909 on facing and polishing rice, the right honourable gentleman had taken, or proposed to take, any steps by propounding an official definition of genuine rice for the purposes of the Food and Drugs Acts or otherwise to prevent the deleterious effects upon public health of the consumption of rice adulterated in the process of polishing by talc or some other glazing agent or in the process of rendering it translucent by petroleum or arachis oil.—Mr. BURNS said in reply: Perhaps I may be allowed to answer both questions together. Copies of the report made by Dr. Hamill of the Local Government Board's Food Department have been circulated to the local authorities concerned in the administration of the Sale of Food and Drugs Act, and I find that action has been taken by them in accordance with the recommendations in that report. As a result a considerable reduction has been made in the amount of extraneous matter left on the rice after the process of facing, and it does not seem necessary to take further action at the present time. I may explain that the process of polishing or facing does not remove any of the nutritive elements of the rice.

Mr. C. BATHURST: Has this report been circulated to the local authorities in London?

Mr. BURNS: A copy of the report which was published in 1909 on the subject to which the question relates was circulated to the local authorities in England and Wales, and these of course include the local authorities in London.

*Medical Examination of Recruits.*

Mr. HUNT asked the Secretary of State for War, seeing that a county association was only allowed one shilling for the medical examination of each recruit, and that the shilling was only paid for those recruits whom the medical practitioner passed, what steps were taken to prevent this small amount of payment having the effect of causing inefficient recruits to be passed.—Mr. HALDANE answered: The grants paid to associations for these and other medical examinations form a common fund from which fees are paid when necessary. There are many cases where fees are not payable as in camp. There is no reason to think that medical practitioners negligently pass medically unfit recruits into the force.

*The Investigation of Plague.*

Mr. CHANCELLOR asked the President of the Local Government Board whether the medical men who were proceeding to China to study the plague would visit places where plague was actually raging and study it on the spot; and whether they would investigate and report on the sanitary conditions of those places, or confine themselves to bacteriological studies in laboratories outside the infected area.—Mr. BURNS (in a written answer) replied: The International Plague Commission, which has been appointed on the invitation of the Chinese Government, will meet at Mukden on April 3rd, and, as at present arranged, will sit from two to five weeks. Dr. Farrar, the British representative, will arrive in the country some time earlier than this so that he may make himself personally acquainted with the local conditions. I am not at present aware of the precise nature of the methods of investigation which the Commission may decide to adopt.

## BOOKS, ETC., RECEIVED.

ARNOLD, EDWARD, London.

Food and the Principles of Dietetics. By Robert Hutchison, M.D. Edin., F.R.C.P. Third edition, revised and enlarged. Price 16*s.* net.

THE Home Secretary gives notice of a vacancy for a Medical Referee under the Workmen's Compensation Act, 1906, for Preston, Garstang, and Chorley County Courts.

# Births, Marriages, and Deaths.

## BIRTHS.

MASINA.—On Feb. 15th, at Jamshed Hall, Nepean Sea-road, Malabar Hill, Bombay, India, the wife of H. M. Másiná, F.R.C.S., of a son.

TIPPING.—On March 1st, the wife of Harold Tipping, M.D. Lond., M.R.C.S., L.R.C.P., of Tyldesley, Palmer's Green, of twin daughters.

WILLAN.—On March 4th, at 23, Claremont-place, Newcastle-on-Tyne, the wife of R. J. Willan, F.R.C.S., of a daughter.

## MARRIAGES.

HOOPER—GOSLIN.—On March 2nd, at St. Mark, Ford, Devonport, Alfred Oswald Hooper, Surgeon, R.N., to Eileen Mary, youngest daughter of the late Lieutenant-Colonel William Charles Goslin and Mrs. Goslin, formerly of Southsea

## DEATHS.

SHAW.—On Feb. 28th, at Middleton Cottage, Southport, Edmund Shaw, M.D., in his 82nd year.

TAPSON.—On March 3rd, at "Holmwood," Clapham Common, Joseph Alfred Tapson, M.R.C.S., L.R.C.P., L.S.A., in his 84th year.

*N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

# Notes, Short Comments, and Answers to Correspondents.

## TRICKING THE MEDICAL MAN.

THAT the publications of the Historical Manuscripts Commission are not altogether such dull reading as some might suppose, but occasionally lapse into a light vein, may be gathered from the subjoined extract from the volume just issued, entitled "Calendar of the MSS. of the Marquess of Ormonde, K.P., Preserved at Kilkenny Castle." Under date "London, April 30, 1681," Colonel E. Cooke, who seems to have been a very lively correspondent, writes to the Duke of Ormond, then Lord Lieutenant of Ireland, a long letter, in which, after communicating certain political intelligence, he proceeds to retail some remarkable stories of the town, this being the first:—

"One habited like the better sort of serving men, having more subtility than honesty, viewing the plate exposed to show in a goldsmith's shop, took a note of it, which reading to the goldsmith as parcels his master (naming a doctor of physic the goldsmith had heard of) had sent him to buy, the goldsmith undertook to furnish him to the value of between 50 *li.* and 60 *li.* The goldsmith and his apprentices immediately fell furbishing up the plate, he appointing to call for it within two hours, because his master was to make a present of it that night. Accordingly he came just as it began to be dark, borrowed one of the servants to carry it, and the note of its weight and worth along with him. As soon as he came to the doctor's house he ordered the fellow to stay in a corner of the hall till he waited on his master, and immediately ascended the stairs to his closet door, and on knocking had entrance, told the doctor he had a kinsman a hopeful young man (exactly describing the goldsmith's servant's person and habit) who from the distemper of this new fever, though he had recovered his strength, yet had so impaired his senses that he frequently fell into raving fits, the warning he gave of their approach was to fall a-talking of plate and money, and money for plate, and then two or three men could scarce hold him; because he had not long been so distempered he the more hoped his recovery, especially encouraged from the doctor's fame; he added he would take care to convey him to the doctor, but durst not come with him, and so left the doctor to give order for a dark room against he came, and returned to the fellow for plate and note to carry to his master, who himself would weigh it, and he would immediately bring down the money. Away slips he out of the back door with his burden, and when the fellow had outstayed his patience he desired to speak with the doctor, to whom when he approached the doctor concluded him to be his bespoke patient, and being in the middle of a recipe bade him sit down and he would discourse with him presently, by his bell summoning up his servants, and as soon as at leisure began to question him how long he had been ill. He, staring, replied that he had not been ill. 'I mean,' said the doctor, 'of this new fever.' He answered he never had it in his life. The doctor would fain feel his pulse; the fellow struggled to prevent it, and began to say he came not for physic, but for money for his plate, or his plate again. Immediately three of his servants were commanded to seize him, and a chirurgeon sent for to let him blood, which by mere force he did, and to take a great quantity from him, nay after sent for a barber to shave off his hair, and the more the fellow argued for his plate or money, the more madman he was accounted, and having lost his blood and hair was clapped into a dark room, not only kept there that night, but the next day also, and the night following. The goldsmith all this while, concluding his servant run away with his plate, was determined to garet him, but a gentleman accidentally coming to the doctor and he mentioning his new patient, the gentleman's curiosity tempted him to see him, who (it seems) the fellow had seen and began to declare whose servant he was. The gentleman knew him not in that disguise, but sending for his master the cheat came out."

## THE PLAGUE IN CHINA: THE SCARE ABOUT CHINA TEA.

A CORRESPONDENT has called our attention to an advertisement appearing in the *Birmingham Dally Mail* under the head of "Black Death in China," with the subtitle "Danger of Plague Germs in the Cheap China Tea now Used in so many Blends." The advertisement goes on to state that fear is entertained in many quarters lest the germs of plague should gain a footing in England through merchandise reaching this country from China—"particularly is this possible in connexion with tea, as owing to the present extremely dear markets all the cheaper teas now being sold are perforce largely mixed with low grade tea from China to bring down the price." We find the suggestion that those who drink China tea may catch the plague to be a very wild and random one, and if it has been made on purely commercial grounds we think that the public has a right to resent the gruesome suggestion. To begin with, the present stock of China tea was probably bonded before the outbreak of plague in China, while the endemic is taking place at an enormous distance from the tea fields or the ports where it is shipped to Europe. These facts, together with the precautions taken by the Board of Customs, render it impossible that China tea should become a vehicle for the spread of plague.

## THE POST OF MEDICAL OFFICER AND PUBLIC VACCINATOR FOR DISTRICT NO. 5 OF PENZANCE.

*To the Editor of* THE LANCET.

SIR,—May I ask through your columns that any medical man who intends applying for this post now advertised as to be vacant on March 16th will first communicate with Dr. C. Branwell, "Bellair," Penzance.

I am, Sir, yours faithfully,

R. C. LAWRY,

Honorary Secretary, West Penwith Medical Society.

Penzance, March 8th, 1911.

## A WARNING.

THE enclosed description has been sent to us by the head of an important pathological laboratory. We publish it as it may safeguard others from being victimised as our correspondent has been. It is quite probable that the man described below has been going around to the British laboratories for some time, and the description agrees with that of a man who fleeced the director of one of the London laboratories about two years ago.

*Description.*—"A short, stout, dyspnœic man, about 5 feet 4 inches in height, aged about 55 years. Jewish-looking, complexion tawny, full head of greyish-white hair, which is slightly curly; similar moustache. Nose thick, and bent slightly to one side. Manners very insinuating; well dressed; American accent. Poses as a medical man and speaks as if he knew prominent colleagues intimately."

We shall be glad to hear from anyone who has suffered from relations with this ingratiating person.

## THE ISLAND OF ST. VINCENT.

IN his annual report on the Blue-book of this colony (an island about 95 miles west of Barbados, 18 miles in length and 11 in breadth, comprising an area of 140 square miles) the Hon. C. Gideon Murray, the Administrator, states that the present population is estimated by the Registrar-General at 53,448. The births registered during the year numbered 1687, of which 951 were illegitimate; marriages numbered 161 and the deaths totalled 831. Public health generally was good during the year. In Union and Mayreu islands, however (two of the Grenadine group), an epidemic of enteric fever broke out. Fourteen cases occurred, each of which was removed to the Carriacou Hospital to be treated there. Efficient disinfective and other precautionary measures were at once adopted, with satisfactory results. It was ascertained that the infection had been introduced from Carriacou (the largest of the group of Grenadines attached to the Grenada Government), where an epidemic prevailed almost throughout the year. The water-supply in the Grenadines is in all cases from wells or tanks. There must consequently always be a possibility of recurrent epidemics of enteric fever until such time as all the public wells of these islands are closed, covered in, and provided with pumps. During the past year a good deal has been accomplished by the Government in this direction.

During the year there were 703 admissions to the Colonial Hospital; the daily average of cases treated was 55; the death-rate was 6·8 of the total cases. Operations numbered 203. The medical officer is greatly assisted in his work by the presence of an efficient European nurse-matron selected by the Colonial Nursing Association. The number of inmates of the Leper Asylum on March 31st, 1910, was 6; during the year there had been 2 admissions and 2 deaths. Under a new Public Health Ordinance the compulsory segregation of lepers is provided for.

The rainfall for the year was 106·77 inches. Rain fell on 236 days the maximum fall in 24 hours being 3·43 inches on June 19th. The mean monthly temperature was 77·2° F.; the maximum was 80·4° (in December), and the minimum 74·6° (in January). Except in August and September, when the atmosphere is uncomfortably hot, although not even in those months insalubrious, the climate may be regarded as most healthy for both Europeans and coloured persons. Malaria is hardly known, while yellow fever has proved itself to be a disease of the past. During the year there was a complete absence of all diseases notifiable under the Inter-colonial Sanitary Convention.

Mr. Murray, in closing his report, observes: "An attempt was made during the year to promote a company for the erection of a really good hotel in the chief port of Kingstown. For the moment the matter is in abeyance, but so soon as the question of steamship communication is settled it will be taken up again. St. Vincent is without good hotel accommodation, which is highly essential if she is to become a resort for health-seekers and travellers, the qualifications for which she possesses in a large degree. The scenery is beautiful; the views are magnificent; the climate, moreover, is one of the healthiest in the West Indies, and from December to April compares favourably with the French or Italian

Riviera. There are charming walks, rides, and drives, and many objects of historic interest may be seen. A fair main road runs all round the island, and there are good bridle-paths in the interior. The sea-fishing and sea-bathing are excellent, while a picturesque natural nine-holed golf-course has just been established in one of the prettiest situations in the island. The more actively inclined will be rewarded by climbing the quiescent volcano Soufrière, which is not difficult of ascent. The volcano has erupted only three times in the last 300 years—viz., in 1718, 1812, and 1902."

## PAYMENT OF THE CHIEF MEDICAL OFFICER OF INSURANCE COMPANIES.

*To the Editor of* THE LANCET.

SIR,—I shall be much obliged to you if through your columns you will kindly inform me how the head office medical officer of an insurance company or friendly society—he who scans the completed proposal schedules—is paid; whether a fixed sum or capitation grant, and how the rate is computed? I am, Sir, yours faithfully,

March 6th, 1911. J. E., F.R.C.S.

*** The principal medical officer of an insurance company is usually paid by salary. The sum varies with the number of days in each week that the officer attends the offices of the company. In the majority of cases the duties include the examination of applicants.—ED. L.

## THE PRUDENTIAL ASSURANCE CO., LIMITED.

THE report of this vast undertaking for 1910 has just been issued. The total number of policies in force in both the ordinary and industrial branches, taken together, numbered at Dec. 31st, 1910, 19,724,323 as against 19,258,033 at Dec. 31st, 1909, an increase of 466,290 policies during the year. The premiums for 1910 amounted to £12,232,438 as against £11,881,877 for 1909, an increase of £350,561. The assets of the company for 1910 amounted to £77,529,226 as compared with £74,201,701 for 1909, an increase of £3,327,525. It is interesting to calculate that the annual premium received in respect of the policies in the industrial branch amounted to an average of not quite 8*s.* each, whereas the average annual premium received for each policy in the ordinary branch was a little more than £5 6*s.* We observe that the company's accounts are set out differently for 1910 and are headed "Assurance Companies Act, 1909, Third Schedule and First Schedule," whereas the Company's accounts for 1909 were headed "Life Assurance Companies Act 1870, Third Schedule and Fourth Schedule." The directors in continuation of the policy adopted last year have considered it advisable to write down certain securities. This is no doubt a wise policy. In the ordinary branch a reversionary bonus at the rate of £1 14*s.* per cent. on the original sums assured has again been added to all classes of participating policies issued since the year 1876, and the directors announce an increase in the rate of bonus in the industrial branch of the company. This small comment can do but scant justice to the huge figures of this company. The best way for those interested is to obtain the accounts themselves and revel in their "millions."

*W. E. L.*—The work, the title of which our correspondent wants to know, is probably "Lectures on Cosmetic Treatment," by Dr. Edmund Saalfeld of Berlin, translated by J. F. Halls Dally, M.D., 5*s.* net, Rebman, Limited, London. It was reviewed in THE LANCET of August 6th, 1910, p. 348.

**COMMUNICATIONS not noticed in our present issue will receive attention in our next.**

## A DIARY OF CONGRESSES.

THE following Congresses, Conferences, and Exhibitions are announced for 1911:—

March 23rd (Paris).—First Congress of French Medical Journalists.
,, 28th–April 25th (Tunis).—Exhibition of Hygiene.
April 4th–7th (London).—Fourth Annual Nursing and Midwifery Conference and Exhibition.
,, 18th–20th (Paris).—Third Congress of Physiotherapy of French-speaking Physicians.
,, 18th (Berlin).—Tenth Congress of the German Orthopædic Surgery Society.
,, 19th–22nd (Berlin).—German Surgical Congress. (Fortieth Annual Meeting.)
,, 19th–22nd (Wiesbaden).—Twenty-eighth German Congress of Internal Medicine.
,, 20th–22nd (Groningen).—Thirteenth Nature and Medical Congress.
May 30th (The Hague).—International Congress on Opium.
May (Washington).—Conference on the Protection of Industrial Property. (Question of False Marking of Goods.)
,, (Paris).—International Sanitary Conference (Prevention of Plague).
,, 30th–June 2nd (London).—National Conference on the Prevention of Destitution.
May–October (Dresden).—International Hygiene Exhibition.
May–October (London, Crystal Palace).—Festival of Empire Imperial Exhibition. (Profits to King Edward VII. Hospital Fund.)
May–October (?) (London, Shepherd's Bush).—Coronation Exhibition.
,, (Los Angeles, Cal.).—American Medical Association.
June 5th–8th (Kolberg, Prussia).—Fifth International Congress of Thalassotherapy.
June and July (Romford).—Town Planning and Modern House and Cottage Exhibition.
July (Bergen).—Seventh Norwegian Congress of Internal Medicine.
,, (Birmingham).—British Medical Association.
July 24th–28th (London).—Second International Congress of Urology.
,, 24th–29th (Belfast).—Congress of the Royal Sanitary Institute.
,, 26th–29th (London).—Universal Races Congress.
August 15th–21st (Dublin).—Royal Institute of Public Health.
,, 30th–Sept. 2nd (Berlin).—Third International Laryngo-Rhinological Congress.
,, 30th–Sept. 6th (Portsmouth).—British Association.
September (Paris).—First Congress of the International Medical Association for the Prevention of War.
,, (Brussels).—Exhibition of Fractures.
,, (Genoa).—International Exhibition of Marine Hygiene.
September–November (Antwerp).—International Exhibition of Alimentation, Brewing, Wines, and Liqueurs.
Sept. 11th–13th (Berlin).—National Congress for the Study and Prevention of Infantile Mortality (*Gouttes de Lait*).
,, 11th–13th (Vienna).—German Urological Society.
,, 11th–16th (The Hague).—Thirteenth International Congress on Alcoholism.
,, 18th–23rd (Sydney).—Australasian Medical Congress.
,, 18th–24th (Turin).—Fourth National Congress of Hygiene.
,, 24th–30th (Rome).—International Congress on Tuberculosis.
,, 25th–29th (Rome) Seventh International Congress of Dermatology and Syphilology.
,, 26th–30th (Brussels).—Third Congress of the International Society of Surgery and Exhibition of Fractures.
October (Cologne).—International Congress of Criminal Anthropology.
Oct. 1st–4th (Liége).—Second Congress of Alimentation.
,, 2nd–5th (Turin).—International Congress of Pathology.
Dec. 4th–9th (Havana, Cuba).—American Public Health Association.
(Date not fixed) (Montreal).—Canadian Medical Association.
(Date not fixed) (Rome).—International Exhibition of Social Hygiene.
(Date uncertain) (Turin).—International Exhibition of Industry and Labour.

In 1912:—
Spring (London).—Second Optical Convention.
July (?) (Cologne).—International Congress of Nurses.
September (Prague).—International Congress of Radiology and Medical Electrology.
September (Berlin).—Sixth International Congress of Obstetrics and Gynæcology.
,, Visit of German Medical Men to America.
Nov. 22nd–29th (Washington, D.C.).—Fifteenth Internationa Congress of Hygiene and Demography.

In 1913:—
(London).—Seventeenth International Congress of Medicine.
(London).—Historical Medical Exhibition. (Organised by Mr. Henry S. Wellcome.)
(Dresden (?)).—International Conference on Cancer.
(Washington).—Congress of American Physicians and Surgeons.
August (Buffalo).—Fourth International Congress of School Hygiene.

In 1914:—
(Vienna).—Third International Congress for Professional Diseases.

In 1915:—
(London).—International Prison Congress.
(London).—Imperial Exhibition (?)

**The following journals, magazines, &c., have been received:**—Paris Médical, Pharmaceutical Journal, Annales de l'Institut Pasteur, Nederlandsch Tijdschrift voor Geneeskunde, Transvaal Medical Journal, Archives de Médecine et Pharmacie Navales, Gazzetta degli Ospedali, Progrès Médical, Boston Medical and Surgical Journal, Canadian Medical Association Journal, Allgemeine Wiener Medizinische Zeitung, Times of India, Pioneer Mail, Presse Médicale d'Egypte, Office International d'Hygiène Publique Bulletin, Medical Record, Il Morgagni, St. Mary's Hospital Gazette, Journal of Mental Science, Journal of Tropical Medicine and Hygiene, Revue d'Hygiène et de Police Sanitaire, Bulletin de la Société de l'Internat des Hôpitaux de Paris, Archives Espanoles de Neurologia, Psiquiatria y Fisioterapia, University of Pennsylvania Medical Bulletin, La Quinzaine Thérapeutique, Cornhill Magazine, Ophthalmic Literature, Magazine of the London (Royal Free Hospital) School of Medicine for Women, Revue de Psychiatrie, Journal of Nervous and Mental Disease, The British Journal of Dental Science, Dominion Medical Monthly, Medical Review of Reviews, The Therapeutic Gazette, The Journal of Laryngology, Public Health, The Nation in Arms, The Zoophilist and Animals' Defender, Guy's Hospital Gazette, Archives de l'Institut Pasteur de Tunis, Annali di Medicina Navale e Coloniale, Archives of Internal Medicine, Dublin Medical Journal, Lady Minto's Indian Nursing Association Report, The Child's Guardian, Revista de Los Hospitales, Indian Medical Gazette, St. Bartholomew's Hospital Journal, St. Thomas's Hospital Gazette, Annual Reports of the Royal Dental Hospital of London, Bulletin of the Johns Hopkins Hospital, Australasian Medical Gazette, The China Medical Journal, The Abolitionist, Proceedings of the Royal Society of Medicine, Edinburgh Medical Journal, Local Government Review, The Contemporary, The Burlington Magazine.

# Medical Diary for the ensuing Week.

## SOCIETIES.

**ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W. (temporary address during building of new house).**

TUESDAY.

SURGICAL SECTION (Hon. Secretaries—Jonathan Hutchinson, L. A. Dunn): at 5.30 P.M.

*Papers:*

Mr. Rickman J. Godlee: Myositis Ossificans and its Results.
Mr. G. H. Makins, C.B.: Myositis Ossificans.
Mr. A. A. Bowlby, C.M.G.: The Formation of Bone in Periosteum separated by Injury.
Mr. J. Berry: Congenital Pouch of the Bladder treated by Excision.
Mr. C. H. Fagge: The Inguinal Method of Radical Cure of Femoral Hernia.
Mr. P. C. Fenwick: Rupture of the Bladder followed by Gangrene.

PATHOLOGICAL SECTION (Hon. Secretaries—C. Bolton, J. C. G. Ledingham), at the Imperial Cancer Research Laboratory, Victoria Embankment: at 8.30 P.M.
Laboratory Meeting.

THURSDAY.

DERMATOLOGICAL SECTION (Hon. Secretaries—H. G. Adamson, J. H. Sequeira), at 11, Chandos-street, W.: at 5 P.M.

*Cases and Specimens:*

Mr. J. E. R. McDonagh: Case of Congenital Xanthoma, with Microscopical Sections.
And other Cases.

FRIDAY.

OTOLOGICAL SECTION (Hon. Secretaries—H. J. Marriage, Sydney Scott), at 11, Chandos-street, W.: at 5 P.M.

*Discussion*

On Trauma in Relation to Otology (opened by Dr. W. Milligan and Mr. C. A. Ballance, M.V.O.).

*Demonstration:*

Mr. Cheatle: Fifteen Temporal Bones illustrating Injuries to the Auditory Apparatus.

Members are requested to send Cases and Specimens illustrating the subject.
Members of the Surgical Section are specially invited.

ELECTRO-THERAPEUTICAL SECTION (Hon. Secretaries—Reginald Morton, G. Harrison Orton): at 8.30 P.M.

*Paper:*

Mr. A. D. Reid: Technique of Skiagraphy (illustrated by lantern slides and a demonstration of a new tube stand).

**MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.**

MONDAY.—8.30 P.M., Dr. N. Raw: The Influence of Diabetes on Tuberculous Infections of the Human Body.—Mr. D'Arcy Power: The Influence of Syphilis on Tuberculous Infections of the Human Body.

**ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.**

MONDAY.—8 P.M., Prof. J. A. Fleming: Applications of Electric Heating. (Cantor Lecture II.)
WEDNESDAY.—4.30 P.M., Col. C. E. Cassal, V.D.: The Adulteration of Food.

**CHELSEA CLINICAL SOCIETY, Chelsea Dispensary, Manor-street, King's-road, S.W.**

TUESDAY.—8.30 P.M., Annual Clinical Debate on the Treatment of Colitis (opened by Dr. W. H. White and Dr. R. Hutchison on Some Principles in the Treatment of Colitis). Followed by a General Discussion. Open to all members of the Medical Profession.

**ROYAL METEOROLOGICAL SOCIETY, Institution of Civil Engineers, Great George-street, Westminster, S.W.**

WEDNESDAY.—7.30 P.M., Prof. H. H. Turner: What Can We Learn from Rainfall Records? (Illustrated by lantern slides.)

**SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos-street, Cavendish-square, W.**

FRIDAY.—8.30 P.M., Dr. R. Strong (Manila): A Note on the Specific Cure of Yaws by Dioxy-diamido-arseno-benzol (with epidiascope).—Dr. J. P. Maxwell (Amoy): The Use of Santonin in the Treatment of the Intestinal Affections of the Tropics.

## LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

**ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East.**

TUESDAY AND THURSDAY.—5 P.M., Dr. A. F. Hertz: Sensibility of the Alimentary Canal in Health and Disease (Goulstonian Lecture).

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.**

MONDAY.—4 P.M., Dr. G. Pernet: Clinique (Skin). 5.15 P.M., Lecture:—Dr. J. Blumfeld: Anæsthetics in Abdominal Operations.
TUESDAY.—4 P.M., Dr. J. Collier: Clinique (Medical). 5.15 P.M., Lecture:—Mr. S. Hastings: Chronic Suppuration of the Antrum.
WEDNESDAY.—4 P.M., Mr. C. Ryall: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. F. J. Wethered: Asthma.
THURSDAY.—4 P.M., Mr. G. B. M. White: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. D. Forsyth: Diagnostic Difficulties in Children.
FRIDAY.—4 P.M., Mr. M. S. Mayou: Clinique (Eye.)

**POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.**

MONDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. Dr. Simson: Diseases of Women. 12 noon: Pathological Demonstration:—Dr. Bernstein. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. S. Edwards: Urinary Surgery.
TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 11.30 A.M.: Mr. Etherington-Smith: Demonstration of Minor Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Mr. Bidwell: Minor Surgery.
WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Dr. Simson: Gynæcological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M., Dr. Simson: Diseases of Women. 5 P.M., Lecture:—Dr. R. Jones: The Question Whether there is an Insane Temperament.
THURSDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12 noon, Lecture: Dr. G. Stewart: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Baldwin: Practical Surgery. (Lecture VI.)
FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Abraham: Cases of Skin Disease.
SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

**LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.**

MONDAY.—2 P.M., Operations. 2.15 P.M., Mr. Turner: Surgery. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4.30 P.M., Mr. R. Lake: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.
TUESDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Wells: Medicine. 3.15 P.M., Mr. R. Carling: Surgery. 4 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.
WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye. 2.15 P.M., Special Lecture:—Dr. F. Taylor: Addison's Disease.
THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. 4.30 P.M., Radiography. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat. 2.15 P.M., Special Lecture:—Dr. G. Rankin: Indigestion.
FRIDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin. 2.15 P.M., Special Lecture:—Dr. R. Bradford: Glycosuria.
SATURDAY.—2 P.M., Operations. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

**NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.**

MONDAY.—Clinics:—10 A.M., Surgical Out-patient (Mr. E. Gillespie), 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Nose, Throat, and Ear (Mr. H. W. Carson).
TUESDAY.—Clinic:—10 A.M., Medical Out-patient (Dr. A. G. Auld). 2.30 P.M., Operations. Clinics:—Surgical (Mr. Howell Evans); Gynæcological (Dr. A. E. Giles). 3.30 P.M., Medical In-patient: (Dr. A. J. Whiting). 4.30 P.M., Lecture:—Dr. A. E. Giles: Diagnostic Difficulties in Gynæcology.
WEDNESDAY.—Clinics:—2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks). 3 P.M., X Rays (Dr. A. H. Pirie).
THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson). 3 P.M., Medical In-patient (Dr. G. P. Chappell). 4.30 P.M., Special Demonstration:—Dr. A. J. Whiting: Selected Medical Cases.
FRIDAY.—2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld); Surgical (Mr. E. Gillespie); Eye (Mr. R. P. Brooks). 3 P.M., Medical In-patient (Dr. R. M. Leslie).

**CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.**

TUESDAY AND FRIDAY.—3.45 P.M., Lecture:—Dr. A. Wylie: Larynx.

**NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.**

TUESDAY.—3.30 P.M., Clinical Lecture:—Dr. H. Tooth: Myopathy.
FRIDAY.—3.30 P.M., Clinical Lecture:—Mr. S. Scott: Otitic Meningitis.

**HOSPITAL FOR SICK CHILDREN (UNIVERSITY OF LONDON), Great Ormond-street, W.C.**

TUESDAY.—5.15 P.M., Demonstration:—Mr. G. E. Waugh: Diseases of Joints—Injuries and Disease of the Hip Joint: Diagnosis, Cause, Complications, Treatment. (Special Post-Graduate Course.)
THURSDAY.—4 P.M., Mr. Addison: Coxavara.
FRIDAY.—5.15 P.M., Demonstration:—Mr. G. E. Waugh: Diseases of Joints—Hip Joint (continued): Sacro-iliac Joint. (Special Post-Graduate Course.)

**ROYAL SANITARY INSTITUTE, 90, Buckingham Palace-road, S.W.**

TUESDAY.—8 P.M., Discussion on Rescue Work in Mines, with a Demonstration of Apparatus in Use (opened by Dr. L. Hill). The following hope to take part in the Discussion:—Prof. J. Cadman, Dr. E. L. Collis, Dr. M. S. Pembrey, Mr. G. B. Walker, and Sergeant A. T. Winborn.

**ST. JOHN'S HOSPITAL FOR DISHASES OF THE SKIN,** Leicester-square, W.C.

THURSDAY.—6 P.M., Chesterfield Lecture:—Dr. M. Dockrell: Treatment (Electrical).

**ANCOATS HOSPITAL,** Manchester.

THURSDAY.—4.15 P.M., Dr. E. B. Leech: Œsophageal Obstruction. (Post-Graduate Clinic).

## OPERATIONS.

### METROPOLITAN HOSPITALS.

**MONDAY** (13th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.), Central London Throat and Ear (Minor 9 A.M., Major 2 P.M.).

**TUESDAY** (14th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.), Royal National Orthopædic (9.30 A.M. and 4 P.M.).

**WEDNESDAY** (15th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

**THURSDAY** (16th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal National Orthopædic (9 A.M. and 3.30 P.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

**FRIDAY** (17th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Royal National Orthopædic (3.30 P.M.), Soho-square (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.), Central London Throat and Ear (Minor. 9 A.M., Major, 2 P.M.).

**SATURDAY** (18th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

**At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.) Hospitals operations are performed daily.**

## EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.*

*Lectures, original articles, and reports should be written on one side of the paper only,* AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale and advertising departments of* THE LANCET *should be addressed "To the Manager."*

*We cannot undertake to return MSS. not used.*

## MANAGER'S NOTICES.

### THE INDEX TO THE LANCET.

The Index and Title-page to Vol. II. of 1910 were given in THE LANCET of Dec. 31st, 1910.

### VOLUMES AND CASES.

VOLUMES for the second half of the year 1910 are now ready. Bound in cloth, gilt lettered, price 16*s.*, carriage extra.

Cases for binding the half-year's numbers are now ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

### TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

| FOR THE UNITED KINGDOM. | | TO THE COLONIES AND ABROAD. | |
|---|---|---|---|
| One Year ... ... ... | £1 1 0 | One Year ... ... ... | £1 5 0 |
| Six Months ... ... ... | 0 12 6 | Six Months ... ... ... | 0 14 0 |
| Three Months ... ... | 0 6 6 | Three Months ... ... | 0 7 0 |

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rate of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

### TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at these rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

## METEOROLOGICAL READINGS.

# The Milroy Lectures
ON
# ANKYLOSTOMA INFECTION.

*Delivered before the Royal College of Physicians of London on March 2nd, 7th, and 9th, 1911,*

BY A. E. BOYCOTT, M.A., D.M. OXON.,
LECTURER ON PATHOLOGY, GUY'S HOSPITAL.

## LECTURE I.

*Delivered on March 2nd.*

MR. PRESIDENT AND GENTLEMEN,—Taking the world as a whole, with the possible exception of the malarial organisms, ankylostoma is, I suppose, responsible for more unhappiness and inefficiency than any other parasite, and, for the most part indirectly, for no inconsiderable number of deaths. Practically all tropical countries are permeated with the worm, and in places where the conditions for its propagation are not unfavourable it may reduce four-fifths of the population to a continual state of chronic ill-health which is only terminated by their premature decease, commonly from some secondary affection. Under circumstances where the prevailing conditions are more or less inhibitory, though most people may be infected, yet in relatively few is the dose of parasite so big or the resistance of the host so small that any demonstrable illness is produced. An individual in whose bowels ankylostoma is living and whose tisssues are shown to be reacting to its presence by changes in the bone marrow, may be said to be infected with ankylostoma in the true sense. But if there are no subjective or objective signs of illness one cannot reasonably say that he is suffering from the disease ankylostomiasis. It is necessary, therefore, to distinguish between cases of ankylostoma infection without illness and cases of ankylostomiasis as sharply as the fact that the one must grade imperceptibly into the other will allow; and to recognise that the latter comprise a variable, and often very small, proportion of the total number of infected individuals.

From the point of view of preventive medicine the worm carrier, owing to his mobility and the fact that his appearance and habits excite no apprehension, is in many ways a more important person than the sick man who is laid by the heels with his anæmia and dyspnœa. I have, therefore, taken "Ankylostoma Infection" as the title of these lectures rather than "ankylostomiasis," and by the latter term I shall refer only to illness due to ankylostoma. We have, unfortunately, no convenient terminology in current use denoting the distinction between "Wurmträger" and "Wurmkranken," "ankylostomés" and "ankylostomiasiques."

In this country ankylostoma is restricted to a very small area—the underground workings of the metalliferous mines in Cornwall; and the persons exposed to infection number in all only some 6000. There is no clear record that any death there has been due to uncomplicated ankylostomiasis. It may therefore well seem presumptuous on my part, whose only personal experience of the parasite has been in Cornwall, to attempt to deal with an infection which, as I have already indicated, attains dimensions of massive importance in the tropics. As a matter of fact, however, the segregation of the saprophytic phase of the parasite to a special and restricted area, and the fact that only a limited proportion of the population is exposed to the possibility of infection, afford opportunities for the study of many of the questions involved which cannot be obtained where infection is intensive and generally disseminated both on the earth and in the people. In the tin-mines of Cornwall, and the coal-mines of Northern France, Belgium, and Westphalia, ankylostoma is confined to subterranean workings, and only those who work in mines run the risk of being infected. The surface in the neighbourhood is, *quâ* ankylostoma, sterile, and the general population live free from infection. In most respects these are the ideal conditions which one would desire to lay down in any experimental inquiry into an epidemic infection; they are seldom realised so satisfactorily in the natural history of disease.

In reference to the personal observations which we have made in Cornwall and in connexion with Cornish cases of ankylostoma infection [1] it should be understood, though their names are not always mentioned, that whatever of interest has come out of these inquiries is mostly due to Dr. J. S. Haldane, reader in physiology in the University of Oxford, and Mr. R. A. Thomas, manager of Dolcoath Mine. To a somewhat less, but by no means small degree, these investigations have been assisted also by Dr. S. G. Scott and Professor J. Cadman.

### THE LIFE-HISTORY OF ANKYLOSTOMA.

The life-history of ankylostoma seems to be now satisfactorily established. The adult worms, male and female, live in the small intestine of man. They eat away at the mucous membrane to which they are attached, with their heads buried more or less deeply into the mucosa and sometimes the submucous tissue. The eggs are laid here in prodigious numbers, and pass out of the human body to begin the saprophytic stage of their existence in the stools. As seen in the ordinary sample of fresh fæces which has been outside the body for several hours, the eggs have generally divided once or twice, so that two or four cells are visible within the transparent shell; unsegmented eggs are not uncommon. Under favourable circumstances development proceeds rapidly through a morula stage to a little worm which hatches out in one or two days; if conditions are unsuitable this period may be prolonged to a week or ten days or even several weeks. The larval worm, after escaping from the eggs, continues its rapid development, moults three or four times,[2] and in four to ten days, according to circumstances, reaches a definite stage—the full grown larva. At this point it is an individual, without any sexual differentiation, about 0·6 mm. long, and is provided with a stout chitinous[3] sheath, inside which it can move about pretty freely. Hence the term "encapsuled larva." Unless it has an opportunity of becoming parasitic no further growth takes place and the full grown larva will continue its saprophytic phase without any further alteration for at least many months. If, on the other hand, it gains entrance to the human body, further progress is made, sexual differentiation becomes manifest, and in about six or seven weeks the adult worm is living in the small intestine.

In the life-history of all parasites it is important to know at what stage or stages multiplication of individuals takes place, and especially whether any increase occurs during any saprophytic phase. For it is clear that it is better worth while to plan one's attack, if any direct attack is desirable, upon the multiplying rather than upon the resting stage. In the case of ankylostoma there is, I think, no doubt that there is no multiplication except during the parasitic phase. The view—first propounded by Giles in his admirable study of kala-azar, and subsequently supported from time to time by various other observers—that ankylostoma larvæ may become sexually mature, and reproduce themselves outside the body, seems to be founded on erroneous observations. Those who have supported the theory of heterogenesis have not sufficiently appreciated the extraordinary prevalence of small nematode worms throughout nature, not parasitic—as far, at any rate, as the higher mammals are concerned, though some of them appear to have important pathogenic relations to plants. Many of them have larvæ which are indistinguishable from those of ankylostoma, especially when in their earlier stages, and on superficial examination their eggs are very similar, though, as far as my experience goes, generally distinguishable on careful comparison. Such nematodes may be found anywhere; they are particularly abundant in fæces which have been lying on the ground in hot moist places, such as mines, where ankylostoma is prevalent. In examining such fæces immediately after

[1] The literature will be found in the Journal of Hygiene, vol. iii. (1903), p. 95; vol. iv. (1904), pp. 73, 437; vol. v. (1905), p. 280; and vol. ix. (1909), p. 264. And in Parliamentary Papers, Cd. 1318, 1902; 1843, 1903; 2066, 1904; 2091, 1904; 4820, 1909.

[2] I do not suppose the number of moults is indefinite or immaterial, but I do not know exactly how many there are. My own observations indicate at least three.

[3] The hard parts of the skin of such animals are commonly described as "chitinous," but not necessarily in all cases in any more precise sense than that in which strong soap solutions or silicic acid are called "gelatinous." Bondouy (Archives de Parasitologie, vol. xiv. (1910), p. 1), at any rate, has shown that the skin of the horse strongyle (*Sclerostoma equinum*) does not consist of chitin—i.e., does not yield glucosamin on decomposition.

collection, and from time to time after subsequent incubation, sexual forms, and then a fresh generation of eggs and larvæ, will often be found; this occurrence is liable to be the more misleading if the fæces are derived from a person infected with ankylostoma, and are found to contain eggs and larvæ which resemble, and in many cases doubtless really are, those of the human parasite.

I have made many attempts to observe the development of sexual forms in cultures of fæces from infected persons, taking care not to introduce any obvious source of contamination, such as earth or the like, and keeping the cultures under aerobic and anaerobic conditions, and with various food materials in different amounts, but in every case without success. The admixture of a little garden earth will often result in the appearance of worms which proceed to become sexual and multiply. Even if occasionally sexual reproduction were observed in fæces which had been effectually protected from contamination, as Ozzard[4] and others appear to have done, I confess that I should interpret the phenomenon as being due to the person having swallowed the eggs of some of the free-living nematodes. Considering the degree to which these animals infest all nature, it seems likely that man must from time to time ingest them or their eggs in fair numbers. Leiper[5] has lately recorded a remarkable instance in which these deceptive little worms appeared in an old laboratory jar.

Apart from the question of heterogenesis, these considerations indicate that one must be extremely cautious in identifying any nematode larvæ which may be found loose in the world as being those of ankylostoma; one cannot, for instance, obtain any evidence as to the infectivity of a place by observations on the prevalence of such larvæ. The only test that I know of which will help to identify ankylostoma larvæ from others which are morphologically closely similar is to keep them under observation and see that no sexual differentiation occurs.

The nematode *Strongyloides intestinalis* is often found along with ankylostoma; one or two cases were seen in Cornwall. The eggs of the sexual parasitic generation (*Anguillula intestinalis*) hatch inside the body and pass out in the fæces as larvæ, which give rise to a sexual saprophytic generation (*A. stercoralis*). It is possible that this has been sometimes mistaken for a sexual saprophytic phase of ankylostoma.

## MODES OF INFECTION.

Up to 1898 it had always been assumed that the only path of entrance of ankylostoma in the human body was the mouth and alimentary canal. Looss,[6] however, then suggested that infection might take place through the skin, afterwards showing that larvæ could penetrate human skin, producing a local reaction, and that men and dogs could acquire the disease by the cutaneous route. Experiments made on man by C. A. Smith, Pieri, Herman, Bruns, Tenholt, and others confirmed these observations. Personally I produced an infection in Professor J. B. Leathes by applying a few full-grown larvæ to the skin of his forearm for a couple of hours. There were a slight local reaction and some itching. As he wrote to me, "σκωληκόβρωτος ἐγιγνόμην," but in the sequel he did better than Herod, and had no symptoms of illness, though definite signs of infection in the form of an increase of eosinophile leucocytes appeared four weeks later; eggs were found in the stools after 50 days. This experiment is, I think, particularly conclusive, since Leathes was at the time working in a chemical laboratory in London, and had never been exposed to any possibility of natural infection. The larvæ used for the experiment were a single batch bred for the purpose from infected fæces in another part of the building with which Leathes had no contact. In the building itself no other ankylostoma material had ever been dealt with.

Of the possibility of larvæ passing through the skin, and ultimately reaching the bowel, there is therefore no doubt. There are also reasons to believe that this is, in nature, by far the most important method of infection. The local reaction due to the larvæ themselves is variable, erythema and urticaria, sometimes hardly perceptible, but though there may not be much to see there is generally a good deal of itching. Scratching and secondary infections from the dirt which accompanies the larvæ often result in the appearance of furuncles, which are such as impress themselves on the subject's memory. Hence the "ground itch" or "coolie itch" of Assam, the "mazamorra" of Porto Rico, the "bunches" of Cornwall. The Cornish miners knew long ago that the agent which lived in Dalcoath Mine, and ultimately led to anæmia, was also the cause of their skin troubles; they were perfectly clear that "bunches" preceded shortness of breath and that the two had some etiological connexion, and produced cogent topographical evidence that one did not occur without the other. I am free to confess that for my own part, having failed to infect myself through the skin, I neglected their epidemiological evidence and was not very much interested in the long tales they had to tell of how they had scratched themselves all night after working in particular parts of the mine, and later on became short of breath. But they evidently knew more about it than I did, and I have often wondered since how many lessons the general consensus of popular opinion has to teach experimental parasitologists.

The obvious difficulties in the way of mouth infection with the stale remnants of human fæces raise the possibility of ingestion being able to give rise to an infection as widespread as that which obtains with ankylostoma under favourable circumstances, where 95 per cent. of the population may harbour the worm. There do not, however, seem to be any conclusive reasons for doubting the importance of mouth infection on this score. Infection with ascaris and trichocephalus certainly takes place by the mouth, since the eggs do not hatch outside the body. All Chinamen are said to have trichocephalus and 70 per cent. of the patients in Paris hospitals[7]; it occurs in as many as 8 per cent. of the random patients in Guy's Hospital,[8] a fact which shows that even in and about London people must swallow the remnants of human fæces more frequently than a consideration of their habits and sanitary circumstances would suggest. Ascaris is rare enough in this country, but occurs in half the agricultural population in Switzerland,[9] and freely in most tropical countries. Of Cornish tin-miners four-fifths have trichocephalus and a quarter ascaris, the frequency of infection with ankylostoma varying from 10 to 90 per cent.

It seems almost impossible that mouth infection among civilised persons should be so frequent, but the facts do not seem capable of any other interpretation. On the other hand, it seems unlikely that the severity of ankylostoma infection, and especially the frequency of reinfection, are compatible with the hypothesis that all the worms are swallowed as larvæ. There is no parallel in bacterial infections, since these can multiply in the body, whereas one ankylostoma larva cannot, if swallowed, give rise to more than one adult worm in the intestines. Most infections with trichocephalus and ascaris seen in this country are slight; but, as in hot countries where the segregation of fæces is imperfect, in Cornish miners some very heavy infections are seen.

In Cornwall, in Porto Rico, and in other places where inquiry has been made, with Egypt as a marked exception, nearly all cases of ankylostoma infection give a history of a skin eruption, characteristically associated with excessive itching in its early stages and often occurring in repeated attacks. Those who fail to recollect any such incident cannot be considered as necessarily examples of mouth infection, since it is known experimentally that the local changes at the point of entrance may be very slight, especially if secondary infections are avoided. But though the skin is doubtless the usual and the important path of entry, there are no reasons for doubting the possibility of mouth infection. Leichtenstern showed that infection follows after swallowing adult larvæ, and I was myself infected in this way through an accident with a pipette. The work of Looss on dogs and of Schaudinn on monkeys has shown that larvæ penetrating the skin get into the veins and ultimately lodge in the lungs, whence they pass up the trachea and down the œsophagus to their definitive home. Some such sojourn in the tissues may be necessary for development; if so, it may be presumed that larvæ which are swallowed escape from the upper part of the alimentary canal and then go through much the same course as those which enter through the skin. But at present there is no

evidence showing that this is the case, and that larvæ when swallowed do not go on straight into the bowel.

Experimental skin infection is not always successful. Pieri, Grassi, and Galli-Valerio, for example, had several failures. I tried repeatedly to infect myself in this way, but with no success, using both cultures containing many adult larvæ and infected fæces obtained in Dolcoath Mine.

Ankylostoma can only gain an effective entrance to the human body in the stage of the full-grown larvæ. Eggs or young larvæ are not infective when swallowed, nor can they pass through the skin. The full-grown larva, with its protective capsule, develops a perfect passion for going through small holes. If water containing such larvæ is filtered through ordinary filter-paper most of them are found in the filtrate. I do not think anyone has ever determined what happens if adult worms are swallowed. Their fate is of no practical importance. The fact that eggs and young larvæ are not infective is, however, most significant, since it means that the fæces of an infected person do not become infective till after the lapse of at least four days, and an individual cannot re-infect himself by immediate contamination as appears to occur with oxyuris.

### DURATION OF INFECTIVITY.

The time-relations of the various stages of development require some notice. From the fresh egg to the full-grown larva may take as little as four days or as long as a couple of months, according to circumstances, the chief factor being temperature. The full-grown encapsuled larva has a moderate natural death-rate when kept under artificial conditions in the laboratory, but out of a good brew a great many are alive at the end of 12 or 15 months, as Looss, Oliver,[10] and I have found, and I daresay would survive a good deal longer. It is a fair assumption that in nature they may live two or three years. This is the less remarkable when we consider that they do not grow or reproduce themselves, and hence have a low metabolism and require very little food. From the time when adult larvæ get into the body till eggs can be found in the stool varies between six and ten weeks,[11] and seems to be the same whether the larvæ are swallowed or get in through the skin. Lambinet[12] showed with dogs that the period was the same whether the larvæ of the dog ankylostoma (*A. caninum*) were applied to the skin, injected subcutaneously, or swallowed.

The duration of life of the adult worm is, no doubt, liable to much variation. In countries infested with the disease opportunities for reinfection are so numerous that it is difficult to obtain satisfactory data. It must also be remembered that recovery from ankylostomiasis by no means necessarily means that the individual is no longer infected. In Cornwall circumstances are better arranged, for there is no chance of reinfection unless the underground workings of the mines are visited. A good many men, after becoming ill with the disease, have abandoned mining altogether. In three such cases we found eggs in the fæces six, four, and four years respectively after the last possible exposure to infection; two of the men were quite well, one was still anæmic. In a good many cases the worms die out in a year or two, or, at any rate, become so few in number that ordinary routine examination fails to find any eggs in the fæces. The recent observations of Bruns, to which I shall refer later, show that the difficulties of accurate diagnosis under these circumstances are considerable. Stiles[13] examined children in the Charleston Orphan Asylum, where infection could almost certainly be excluded, and found that three were still infected after six years' residence. Ashford,[14] in Porto Rico, in a similar institution found, among 45 girls, four who were infected after four years.

Taking the whole saprophytic and parasitic cycle together, the time from the first infection of one individual to the establishment of an infection derived from him in a second person may vary from seven weeks to at least six years. The recipient of infection does not himself become infective for about seven weeks. An infected place may become infective four days after eggs have been deposited there, and may remain infective for at least a year.

### THE TWO CAUSATIVE ORGANISMS.

From the parasitological point of view, the specificity of the causative organism constitutes an integral part of the conception of the individuality of an infective disease; the medical mind pays attention rather to the congeries of symptoms; while to the epidemiological sense the circumstances which condition prevalence in place and time more particularly appeal. The classification and nomenclature of diseases must necessarily vary with the particular trend of the systematist concerned; the real difficulty obviously begins when a compromise has to be made between the different principles which I have indicated without diverting an undue amount of time and trouble into the barren fields of terminology. With complete knowledge the parasitologist, the physician, and the epidemiologist will, no doubt, all find their lines of thought in harmony, but meanwhile one has to recognise that there is some inconsistency in having one disease, ankylostomiasis, which may be caused by either or both of two parasites which are specifically or, as some would have it, even generically distinct. In 1902 Ashford and Stiles showed that most of the ankylostomiasis in the southern regions of the United States and in Porto Rico was not due to *Ankylostoma duodenale*, but to a hitherto unrecognised species, *Ankylostoma* (*Necator*, *Uncinaria*) *americanum*. *A. americanum* is distinct enough from *A. duodenale*: the worms themselves are smaller, the eggs rather longer and narrower, the mouth has no recurved hooks, and the genital armature of the male is different. Since its original discovery it has been found in all parts of the world. If sufficient search were made it is pretty certain that both species would be found everywhere that ankylostomiasis is prevalent. On general grounds one would surmise that in any given locality one of the two species is probably autochthonous, and that the other has been introduced. *A. americanum* has not been identified in Cornwall, probably because comparatively few adult worms have been collected for detailed examination. Where both species are abundant individuals are often doubly infected; thus in Panama Whipple,[15] in 273 necropsies, found 39 with *A. duodenale* alone, 49 with *A. americanum* alone, and 25 with both. As far as is known, there is no clinical variation in cases of ankylostomiasis which can be correlated with the causative species of parasite. It is possible that the extraordinary divergence of the experience of different observers on certain points—the presence and abundance of blood in the stools, the relative efficacy of various anthelmintics, and so on—would be explained by taking into consideration this question of species. So far, however, no one seems to have started from the point of view that duodenaliasis should be distinguished from americaniasis. The term uncinariasis which is in use in America was born of the zoological passion for antiquarian research; it does not signify a specific infection with *Uncinaria americana*, but is synonymous with ankylostomiasis. In passing, one can only express one's relief that no organised attempt has been made to apply the law of priority to the nomenclature of disease.

Both species are restricted to man and probably the higher apes; experimental infections have been achieved occasionally in monkeys, and, as far as the earlier stages are concerned, in dogs and guinea-pigs. Other animals have ankylostomes of their own; dogs, cattle, sheep, seals have each their own species, none of which are naturally infective for man. Other parasitic nematodes (strongyles), which are widely distributed in domestic and other animals, have eggs which on casual inspection resemble those of ankylostoma; hence the notion that man might contract the infection from horses, and the statement lately printed in a reputable journal that the human parasite occurs in hens and other domestic animals.[16]

### THE SYMPTOMS OF ANKYLOSTOMA INFECTION AND ANKYLOSTOMIASIS.

The skin symptoms associated with ankylostoma infection are of two kinds. 1. Resulting from the irritation caused by the larvæ penetrating the skin, there may be a local erythema or urticaria, varying greatly in severity in different cases, and often, from secondary infections, going on to pustules and furuncles. It may be that the organisms causing these secondary infections—in the cases I have examined they were

[15] American Journal of the Medical Sciences, vol. cxxxviii. (1909), p. 40.

[16] Journal of Tropical Medicine, vol. xii., 1909, p. 333.

staphylococci—are actually carried into the subcutaneous tissues on the larvæ; this is the less probable if, as is stated, the larvæ leave their outer skins behind them when they penetrate the hair follicles. 2. At any time after infection, sometimes months or years after the subject has been removed from any chance of a fresh invasion, attacks of generalised urticaria may occur, as with hydatids and *Filaria medinensis;* in other cases a general pruritus, without any local changes, causes a good deal of trouble.

During the first few weeks after infection there may be a slight bronchial catarrh and trivial pains in the upper part of the abdomen which bear no relation to the taking of food. These symptoms are no doubt due to the worms passing through the lungs in the course of their development, and to the irritation which they cause when they first reach the bowel. Manouvriez, describing the anæmia of coal-miners in France in 1878 without any idea that it was a parasitic disease, draws attention to the regular occurrence of urticaria and boils, and notes that a bad attack is generally accompanied by bronchitis (*catarrhe des gourmes*). Leathes also noticed a slight catarrh soon after his experimental infection.

These symptoms in the skin, lungs, and bowels may be very slight and may easily escape notice, so that an infection may readily become established without attracting the recipient's attention. In a certain number of cases, however, the individual becomes anæmic, and the severe symptoms which constitute the disease ankylostomiasis supervene. Various writers have described symptoms in ankylostomiasis which are not due to the anæmia, but represent, in their opinion, a direct toxic action of some product of the worm on the economy. Siccardi [17] has recently strongly urged that some such explanation is required for the occurrence of nervous symptoms (easy cerebral and muscular fatigue, apathy, melancholia, amblyopia with a central scotoma) in infected persons who are not anæmic. As a rule, however, these symptoms are not prominent, and are overshadowed by the dyspnœa, dyspepsia, and general upset of all the organs of the body, which may reasonably be ascribed to the anæmia. That a toxic substance is absorbed into the body is, however, clearly shown by the occurrence of urticaria and by the almost constant response of the eosinophile leucocytes in the bone marrow.

The incidence of anæmia in infected persons appears to be determined by three factors—individual susceptibility, dose of infection, and frequency of infection. It is significant that the proportion of infected persons who are anæmic is in general parallel with the proportion of the whole population who are infected, especially in the sense that severe anæmia is seldom found unless the infection is very prevalent. Thus in Cornwall, in Dolcoath Mine, 95 per cent. of all underground hands were infected, and about 5 per cent. of those infected were ill to a material degree; in Grenville 15 per cent. and in Tincroft mine 10 per cent. were infected, and there was only a single case of illness in 800 men. In the Belgian coalfield 4 per cent. of the men are now infected, and cases of severe anæmia are unknown. In Porto Rico, on the other hand, where the whole agricultural population was infected, about half had less than 50 per cent. hæmoglobin, and suffered from a severe grade of the disease.

If, then, the prevalence of infection is slight, the incidence and severity of illness will be correspondingly low.[18] This relation does not necessarily hold for bacterial infection, where the infective agent can multiply inside the body. With ankylostoma this, of course, does not occur, and the evident connexion between prevalence and severity points clearly to the quantity of infection being an important factor in determining illness and correspondingly reduces the significance of individual susceptibility. Abundant contact with larvæ means, as a rule, that most people will be infected, that the proportion who receive large doses will be considerable, and that frequent reinfection will occur. It is difficult to separate the two last factors, for each reinfection swells the total number of worms in the body. There are, however, certain facts which indicate that the same total of worms will be more effective in causing anæmia if it be taken in divided doses rather than in a single massive infection.

It has been frequently observed—and in Cornwall the evidence is particularly clear—that if an anæmic person is removed from the infected place he often rapidly improves, and may recover completely without any specific treatment. Some natural decrease in the number of worms must go on, but at least as many may still remain when the anæmia has disappeared as are found in anæmic individuals who are constantly exposed to reinfection. This suggests that the maximum effect of infection is exerted soon after the worms reach the intestine, and that subsequently, as far as that particular batch is concerned, the host becomes relatively immune. Further, that frequent reinfection is a potent factor in producing the more severe grades of anæmia, apart from the contributions which are in this way made to the total mass of infection.

Of individual susceptibility we only know that some individuals do not become ill, though they harbour many worms and are exposed to infection and reinfection equally with very sick persons. As regards the supposed racial immunity of negroes, the exact observations of Ashford [19] suggest that the blacks, with an equal dose of worms, are as susceptible to anæmia as others, but that under the same circumstances of exposure they do not become so heavily infected. If the influence of variations in habits can be excluded, this indicates a resistance to infection rather than a resistance to the consequences, a relative immunity to the parasite and not to its poisons. There is, however, no definite evidence that anybody is definitely resistant to infection in the sense that ankylostoma will not live in him. With free exposure to larvæ, in only 2 to 5 per cent. of individuals is infection not discovered; this might easily be accounted for by defective diagnosis.

### THE PATHOLOGY OF ANKYLOSTOMA ANÆMIA.[20]

The anæmia of ankylostomiasis may reach a very severe grade, cases with 15 to 30 per cent. hæmoglobin being common in heavily infected places.[21] Thus, of the 61 cases described in detail in the second report of the Porto Rico Commission, 46 had less than 30 per cent. and 18 less than 20 per cent. hæmoglobin. Estimations of the total quantity of hæmoglobin in the blood show, however, that the percentage content of hæmoglobin does not correspond to the actual deficiency, owing to a considerable increase in the plasma and the total volume of the blood. In the following table are given the results of determinations made by the carbon monoxide method [22] of Haldane and Lorrain Smith on three Cornish cases; for comparison I give the corresponding averages for normal persons (Haldane and Lorrain Smith); for cases of chlorosis, pernicious anæmia, and anæmia from hæmorrhage (Lorrain Smith); and for cases of splenomegalic polycythæmia (Boycott and Douglas). The figures are all corrected for variations in body-weight and are expressed as for a standard individual of 60 kilogrammes.

| — | Hæmoglobin per cent. | Total hæmoglobin: grammes.* | Blood volume cubic centimetres. | Relative number of red cells in whole blood. |
|---|---|---|---|---|
| Normal ... ... ... ... | 100 | 400 | 3000 | 100 |
| Ankylostoma No. 1 ... | 44 | 311 | 5160 | 102 |
| ,, No. 2 ... | 47 | 357 | 5520 | 106 |
| | 41 | 331 | 5880 | |
| ,, No. 3 ... | 49 | 316 | 4620 | 128 |
| Chlorosis ... ... ... | 40 | 354 | 6480 | 173 |
| Pernicious anæmia ... | 26 | 179 | 5160 | 32 |
| Anæmia from hæmorrhage ... ... ... ... | 33 | 175 | 3900 | 73 |
| Polycythæmia ... ... | 162 | 1360 | 6000 | 400 |

* The assumption is made that 1·34 cubic centimetres of oxygen combine with 1 gramme hæmoglobin; the actual determinations are made in terms of oxygen capacity.

[17] Archives de Parasitologie, vol. xiii., 1910, p. 555.

[18] There are, of course, exceptions.

[19] Anæmia in Porto Rico, 1905, p. 10.

[20] Anæmia denotes a deficiency in the concentration (not the total quantity) of hæmoglobin in the blood.

[21] Records as low as 9 or 10 per cent. hæmoglobin are suspicious; the Fleischl instrument reads too low at the bottom of the scale. The worst case we had in Cornwall had 17 per cent. on the Haldane-Gowers hæmoglobinometer.

[22] The experimental proof that this method gives substantially correct results will be found in the Journal of Physiology, vol. xxxiii., 1906, p. 493, and the Journal of Pathology, vol. xiii., 1909, p. 256.

On the whole, therefore, in ankylostoma anæmia there is comparatively little shortage of hæmoglobin, nearly the whole of the anæmia being due to an increase in plasma. The condition, indeed, is a hydræmic plethora like chlorosis, and quite different from pernicious anæmia and anæmia from hæmorrhage, in which there is a more or less grave defect in the total quantity of hæmoglobin in the blood.

The colour index is characteristically low, and becomes lower as the grade of anæmia becomes more intense. Hence the total number of red cells in the body may be greater than normal. In a case of moderate severity—40 per cent. hæmoglobin—the morphological changes in the red cells are very few. There is some variation in size, most of the abnormal cells being too small, and a little poikilocytosis, but one does not find any marked signs of active regeneration of red cells (polychromasia, punctate basophilia, nucleated red cells), presumably because the whole blood contains about as much hæmoglobin as, and actually more red cells than, normal. In severe cases such changes appear in varying degrees, because, with a great increase of plasma, the rate of circulation cannot be sufficiently accelerated to carry an adequate quantity of hæmoglobin through the lungs in unit time. In all these particulars there is a great similarity to chlorosis, and a sharp contrast with pernicious anæmia. Occasionally in ankylostomiasis, as in anæmia from malaria and malignant disease, blood formation becomes more embryonic, and large cells with a high colour index are found.

In the relation of symptoms to the degree of anæmia there is a further similarity between these two states of hydræmic plethora. It is characteristic, and has been noted by Ashford and others, that in ankylostomiasis a pretty severe degree of anæmia may be associated with a surprising capacity for work. Thus in Cornwall men with less than 40 per cent. hæmoglobin were doing their regular work in the mine, and of men with between 40 per cent. and 50 per cent. hæmoglobin our notes record "feels quite well," "no symptoms," though their occupation entails a great deal of muscular effort. In the same way a chlorotic anæmic to the same degree will be fairly active, while cases of pernicious anæmia are obviously very sick people by the time their hæmoglobin has fallen to 40 per cent.

### SOME THEORIES AS TO THE CAUSE OF THE ANÆMIA.

As already noted, our cases of ankylostomiasis had a real deficiency of hæmoglobin amounting to about 15 per cent. Without further information it is not possible to say whether this is due to the fact that they were working men, and on the whole decidedly less well nourished than the laboratory workers who furnished the "normal" data,[23] or whether there is actually some loss of blood from, or destruction of blood within, the body, which would account for a deficiency of this degree. Most observers have assumed that the blood volume is unaltered, so that the concentration of hæmoglobin in the blood is a measure of the total quantity; in other words, that a patient with 20 per cent. on the scale of the hæmoglobinometer has only one-fifth of the normal amount of hæmoglobin in his whole blood. They have therefore sought for reasons why so much blood should disappear.

The original idea was that the worms themselves suck blood.[24] This they undoubtedly do, for blood may be found in their alimentary canal, though, as a rule, in only a proportion of the worms obtained by the action of anthelmintics or post mortem. It is, however, not certain that this represents the natural condition. Whipple has pointed out that the worms may be observed to void blood, and it is possible that the empty individuals are to be accounted for in this way. Looss is of opinion that the normal food of ankylostoma is the mucous membrane, and that they only take in blood accidentally when they happen to penetrate a vessel. They do not seem to make much headway in digesting red corpuscles; on the other hand, it may be chiefly plasma that they are after. Many observers have expressed a natural hesitation in believing that such severe anæmia can result from the abstraction of such small amounts of blood; for, whether the worms digest it or not, the quantity must be small, else blood, or remains of blood, would be constantly present in the stools.

Actual enumeration shows more bites than correspond to the number of worms found post mortem. It has therefore been suggested that the worms often let go their hold on the wall of the bowel to take a fresh grip elsewhere, and that their old bites continue to bleed. In support of this hypothesis Loeb and Smith[25] found that extracts of the head-end of the worm inhibit coagulation of the blood, as also did Noc.[26] If this accounted for the anæmia, the stools ought to contain obvious quantities of blood. Sometimes they do, as may occur in any severe anæmia, and with massive infections with ankylostoma produced experimentally in dogs (Looss), but in the majority of cases blood is very seldom found.

Others have sought to show that blood is destroyed inside the body, and in this connexion have described the occurrence of hæmolytic substances in the bodies of the worms. Weinberg[27] found a hæmolysin in the allied nematode of the horse (*Sclerostomum equinum*), Preti,[28] Noc, Alessandrini,[29] and Calmette and Breton various similar substances in *A. duodenale* and *A. americanum*. Noc and Blasi[30] describe isohæmolysins in the serum. Loeb and Smith found no hæmolysin, but Whipple[31] found a very weak hæmolysin in *A. duodenale*, *americanum*, and *caninum*. Whipple thinks, however, that it is very unlikely that this weak hæmolysin can have any relation to the anæmia of ankylostomiasis. He points out that extracts of trichocephalus may be equally hæmolytic; cases of trichocephalus anæmia have been described,[32] but their etiological connexion with this common parasite is extremely doubtful. Whipple also found that ankylostoma may be embedded in the mucous membrane of the human intestine in small cysts filled with blood, and that this blood is not hæmolysed—almost conclusive proof of his contention that such hæmolysins as are present are quite negligible.

Even if hæmolysins were present in large amounts they could not be regarded as being the cause of the anæmia unless evidence of actual hæmolysis in the body were obtained. No such evidence exists. The amount of iron in the liver is normal[33] instead of being much increased, as it is when excessive destruction of red cells occurs (pernicious anæmia, malaria); and determinations of the total amount of hæmoglobin in the blood show that only about one-tenth is missing altogether; this might easily be accounted for by the small amount lost by the sucking of the worms and the bleeding of their bites.

A certain number of cases when quickly improving show some degree of polycythæmia, the red cells rising to between 6 and 7 millions per cubic millimetre.[34] This is clearly the same phenomenon as is well known in chlorosis, and is due to a rapid concentration of blood containing in all too many red cells of a low colour index. Weinberg and Leger[35] are, however, ingenious enough to see in it an indication of the effect of repeated small doses of hæmolysin, which, as Cantacuzène[36] showed, may stimulate the marrow.

A good number of worms acting for some time can cause ultimately a marked degree of sclerosis of the intestine, with atrophy of the mucous membrane. It is difficult to see how this can have much to do with producing the anæmia, though the probability of some impairment of nutrition and delay in recovering from the effects of the anæmia must be considered.

The essential change in the blood, therefore, is an increase in plasma, with a secondary, compensatory reduction in the colour index. There is probably also a small defect in the total amount of hæmoglobin, which may be attributed to the local action of the worms in the bowel. The response to this loss may be imperfect owing to the prolonged oxygen starvation of the marrow itself.

ABSTRACT OF

# The Hunterian Lectures

ON

# THE ANTHROPOLOGY OF ANCIENT BRITISH RACES.[1]

*Delivered before the Royal College of Surgeons of England on Feb. 20th, 22nd, 24th, and 27th, and March 1st and 3rd, 1911,*

BY ARTHUR KEITH, M.D. ABERD., F.R.C.S. ENG.,

CONSERVATOR OF MUSEUM, ROYAL COLLEGE OF SURGEONS OF ENGLAND.

## THE ANTIQUITY OF MODERN MAN.

IN a series of six Hunterian lectures on the above subject, given recently in the theatre of the Royal College of Surgeons, Professor Keith described the human remains found in the Upper (100 feet) gravel terrace of the Thames Valley at Galley Hill, near Northfleet. The remains, which are now in the collection of Mr. Frank Corner, M.R.C.S., were found by the late Mr. Robert Elliott towards the end of 1888, and although at first there was a considerable number of geologists who refused to regard these remains as equal to the 100 feet terrace in point of time, yet a fuller consideration of the evidence produced by Mr. E. T. Newton, F.R.S., had recently convinced experts both at home and abroad that these remains were embedded when the level of the Thames was 90 to 100 feet higher than it is to-day. The antiquity of the Galley Hill man must be measured by the work done by the Thames since that time. The river has not only worn its estuarine valley down 90 to 100 feet owing to an elevation of the land, but in the opinion of experts has also eroded and filled up a channel from 40 to 50 feet below its present level. Measured at its lowest estimate, the Thames bed has been lowered and raised at least 170 feet since the Upper terrace of gravel was laid down in post-Glacial times. Seeing how little the level and aspect of the valley have altered since the Roman period, and that there is no reason to presume that changes in level and in climate occurred at faster rate in past times than in the present, one may safely allow a period of 1000 years for every foot which the river has worn away or laid down. On this basis of computation the antiquity of the Galley Hill remains may be estimated at 170,000 years—probably an under-estimate.

A consideration of the parts of the skeleton found at Galley Hill shows how old the modern type of man is. The Galley Hill man, although differing in several features, is essentially the same in structure and form as the man of to-day. He was a little over 5 feet in height, round-chested and narrow-shouldered, with a well-developed muscular system. His brain development may be estimated from the stone implements found in the Upper terrace gravel, from the size of his cranial cavity—1360 cubic centimetres, a fair endowment when his small size is kept in view—and from a cast of that cavity which reveals a highly convoluted brain showing all the essential features of the modern brain. From the moulding of the lower jaw we may safely infer that speech was developed; his teeth and muscles of mastication do not differ markedly from later men of the Neolithic period. His face was short and his forehead of a type quite common amongst modern men. His peculiar features are the extreme length and narrowness of the head (the width is about 67 per cent. of the length), the shape of the upper and lower extremities of the thigh bones, and the shortness of the leg bones.

The Galley Hill man is the only representative known of the thousands of generations of Englishmen which span the vast period of human life in this country from Glacial to Neolithic times. We may safely presume, said the lecturer, that the relatively long-headed men of Neolithic times and similar modern types still to be found amongst the inhabitants of the western parts of Great Britain and Ireland are directly related to Palæolithic man. How far the single individual found at Galley Hill represents the type of man prevalent in palæolithic England remains to be seen, but the discovery last year in France by Herr O. Hauser of a man of similar type in a stratum which overlies that in which the Neanderthal race is found, shows the existence of the same type of man on the continent during the long Palæolithic period. Similar discoveries have been made in Belgium, Bohemia, and Moravia, and it is reasonable to conclude that the Galley Hill type was widely spread in Europe during the Palæolithic period.

## PRE-GLACIAL MAN.

Professor Keith reminded his audience that the Galley Hill bones, by far the earliest known human remains yet found in England, took one only a little way back in the most recent chapter of the earth's history. The period of the Galley Hill man was certainly post-Glacial. Until a little over three years ago we knew nothing of the pre-Glacial ancestors of man in Europe, but in 1907 a lower jaw of a human being was discovered in a stratum which geologists regard as a formation laid down by a river before the first Glacial period had settled on Europe. The sandpit in which the mandible was discovered is situated in Baden, in the valley of the tributary of the Neckar, some eight miles from Heidelberg. Professor Keith said that great credit was due to Dr. Otto Schoetensack, professor of anthropology in the University of Heidelberg, for the splendid monograph which has been published concerning this remarkable "find." The importance of the Heidelberg "find" lies in the fact that for the first time it is possible to form a conception of the stage of evolution reached by man in Europe after the Pliocene period had closed and before the Glacial period had set in. The teeth do not differ to any great degree in size and shape from those of the more primitive races of modern time. The rotatory or side-to-side movement of the teeth, which distinguished man from all known anthropoids, was already evolved; the canine tooth had taken its place in the uniform human dental series. The long framework of the jaw is so massive that at first sight it appears more anthropoid than human. It is clear that the muscles of mastication were developed to an extent far beyond that known in any other human race, and it may be safely inferred that, whatever the nature of the food consumed may have been, great muscular force was necessary for its pulverisation. The lower jaw takes an important part in the mechanism of speech; certain characters of the modern jaw are regarded as adaptations to a faculty which distinguishes man from all other beings. These speech characters in the Heidelberg jaw are of an intermediate nature; they appear to represent a stage in the evolution of the human chin as we know it from a simian condition. The parts appear ill adapted for speech, and at the most only a primitive stage in the evolution of language could have heen reached.

The remains of the individual (*Pithecanthropus erectus*) found in Java 20 years ago by Dr. Eugene Dubois, now professor of anthropology in the University of Amsterdam, correspond in point of time—so far as time can be determined by the fossil plants and animals found with the remains—to the Heidelberg remains. It would be of great interest to compare these two individuals—so far apart in space and yet associated in point of time—but unfortunately we know nothing of the mandible of Pithecanthropus erectus and nothing of the skull of Homo Heidelbergensis. In Pithecanthropus the femur is not unlike the modern human thigh bone; it has all the characters associated with erect posture. Professor Dubois estimated the brain to be intermediate in point of size to the modern human and anthropoid brain. The only point which offers a standard for the comparison of the pre-Glacial man of Java with the Heidelberg remains is the last molar teeth. We know the character of the last upper molar of Pithecanthropus and the last lower molar of the Heidelberg man. In point of size the two are comparable; the system of mastication was certainly the same in both and the palate of the one was probably not very different from that of the other. The Heidelberg, however, seems too massive and large to be fitted to the calvarium of Pithecanthropus. These two individuals from Germany and Java represent all that is yet known of the pre-Glacial ancestors of man.

## THE NEANDERTHAL RACE.

Professor Keith described the progress which had been made during the last four years in our knowledge of the Neanderthal race. The researches of archæologists and

anthropologists in the south-western districts of France—especially along the valley of the Dordogne—were making good the blank in our knowledge of man in Europe during the Glacial and post-Glacial periods. The Neanderthal race was clearly the successor and probably direct descendant of pre-Glacial man, so far as may be judged from the scanty remains of that human type found in Heidelberg and Java. Notwithstanding the recent discovery of three individuals of the Neanderthal race in the valley of the Dordogne during the last four years, the cranium brought from Gibraltar in 1864 by the late Mr. George Busk, F.R.S., at one time President of the Royal College of Surgeons of England, and now lodged in the Museum of the College, still remains the most valuable document relating to the physical characters of the race, for in no other specimen are the bones of the face and floor of the cranial cavity so perfectly preserved, and none show so close a relationship to the known characters of pre-Glacial man. The Gibraltar specimen has had a chequered history; quite recently Colonel R. E. Kenyon discovered in the minutes of the Gibraltar Scientific Society that the skull was found and presented to the society by its secretary, Lieutenant Flint, R.A., in 1848, eight years before the Neanderthal calvarium was discovered in South Germany. It was seen and examined by Huxley, who, although he had just completed his famous memoir on the Neanderthal calvarium, did not fully recognise its important bearing on the early physical history of man. The French anthropologists MM. Quatrefages and Hamy assigned the Gibraltar specimen to the Neanderthal race in 1885, and then it passed into obscurity until 1908, when Professor Sollas of Oxford University recognised its importance and again drew the attention of European anthropologists to it by an elaborate and accurate description in the Philosophical Transactions. It is now very clearly recognised, said the lecturer, that although it was a very easy matter to recognise the sex of the living person from the features of the face and head, it was not unfrequently impossible to determine sex from an examination of the skull. So far all the crania of the Neanderthal race discovered have been assigned to the male sex; Professor Sollas came to the conclusion that the Gibraltar specimen represented a female of that race. The question of sex as regards the Gibraltar specimen must be left open, for its peculiar features may be explained by supposing it to belong to an earlier and more primitive human type than the Neanderthal race. While the cranial capacity, which may be taken as an index of size of brain, is above the average of modern man in the typical members of the Neanderthal race, that of the Gibraltar individual is much below—about one-fifth less. The nose of the Gibraltar individual must have formed a remarkable feature, quite unlike any form now known to exist, but very probably the precursor of the prominent nose of the modern European. In some features, especially in the region of the face between and below the eyes, the condition in the gorilla was recalled. Recently Colonel Willoughby Verner had presented a thigh-bone to the Museum of the Royal College of Surgeons of England which he discovered in a cave previously unexplored in the neighbourhood of Gibraltar. This bone, that of a person almost a pygmy in stature, was quite unlike any human thigh-bone now known and indicated a peculiar race. From the bones of other animals found with it a degree of considerable antiquity may be presumed for this recent discovery.

### THE EVOLUTION OF THE MODERN TYPE OF MAN.

Professor Keith analysed the various factors that appeared to have played a part in the evolution of the modern type of man. The characters of the Neanderthal man—the successor of the pre-Glacial European—were such that there could be no doubt, in spite of the largeness of his brain, that he was more simian or primitive in the scale of evolution than any other known form, past or present, with the exception of his predecessor, pre-Glacial man. A little over a year ago Herr O. Hauser discovered in the lower Aurignac stratum of the valley of the Dordogne, the stratum which immediately overlies the Mousterian beds in which the remains of the Neanderthal race are found, the skeleton of a man of the modern type and closely related in feature and stature to the Galley Hill remains, the oldest yet found in England. The modern type appears, from this discovery, to follow quickly on the heels of the Neanderthal type. To account for the sudden appearance of the new type Professor Klaatsch of Breslau, who has made a very minute examination of the skeleton lately found in France, has formulated the theory that man may have been evolved on several occasions and from different stocks. The Neanderthal race, because of certain gorilla-like features, he regards as having sprung from the same stock as that anthropoid, while the Galley Hill or modern type has been evolved from the basal stock of another anthropoid—the orang. In the lecturer's opinion Professor Klaatsch's theory was untenable, and the explanation was to be obtained from another source. In 1885 Dr. Pierre Marie, the well-known Parisian physician, described a peculiar disease of growth which he named acromegaly—a disease in which various parts of the adult body begin to grow, especially certain parts of the face and head, but all the bones, muscles, and soft parts are increased in bulk, especially those of the hands and feet. The parts which are chiefly affected in the unfortunate victims of this disease are those which obtain such a remarkable development in Neanderthal man. It is further known that the condition of acromegaly is connected with a disturbance in the functions of the pituitary gland. The evidence now accumulating suggests that this gland furnishes the tissues of the body with a substance (internal secretion) which so sensitises them that they hypertrophy when subjected to a degree of exercise which would not affect the normal tissues of the body. In anthropoids—in the most primitive races of man—this pituitary influence was evidently very marked. The explanation of the problem relating to the evolution of the modern from the Neanderthal type of man was most likely to be found in a more complete knowledge of the exact part played by the internal secretions of the pituitary and other glands with the growth of the body. On the evidence available we are justified in assuming that the evolution of the modern type of man was consequent on a change in the function of the pituitary gland. No doubt the amelioration of the conditions of life which arose with the dawn of human knowledge had also played a part in the evolution of the modern type, but the exact manner in which environment influences heredity is still obscure.

### PREHISTORIC BRITISH TYPES OF MAN.

With the steady increase of evidence the antiquity of man in Britain receded into a more and more remote past. No fossil remains of Glacial or of pre-Glacial man had yet been discovered in England, but it is certain from the stone implements left behind that at least the southern part of the country was inhabited. It is highly probable that fossil remains of this race will yet be found, and will show that these very early Britons were of the Neanderthal type. At present our knowledge of the physical characters of the inhabitants of Britain commences with the Galley Hill man from the Upper terrace of the Thames Valley. The subsequent period is a long blank, but the cranium found by Mr. W. M. Newton in a gravel pit near Dartford in 1902 may prove to have an antiquity represented by the Lower terrace of the Thames Valley. The geological evidence relating to this skull, which the discoverer has presented to the Museum of the College, is open to question until further discoveries of a similar nature are made. The Dartford cranium is of the Cromagnon type; it is known from the discoveries made in the caves (Grimaldi) near Monaco and in those of the Dordogne Valley in France that the Cromagnon race succeeded the Galley Hill race; it is possible that this may also be found to be the case in England. If the Dartford skull be excluded from the list of authentic documents, then the remains which succeed those of Galley Hill in antiquity are the human bones found during the excavation to form the Tilbury Docks in 1883 and which were fully investigated and described by Sir Richard Owen and are now preserved in the British Museum (Natural History), South Kensington. The remains of the Tilbury individual were found at a depth of 34 feet under alternate layers of mud, clay, and peat which had been formed during the slow subsidence of the river bed since these human remains were imbedded in the sands. The remains lie over a gravel bed situated 130 feet below the terrace in which the Galley Hill man was found. If, as a working hypothesis, a subsidence of a foot for each 1000 years be allowed, and the rate may be less, an antiquity of 30,000 years may be assigned to the Tilbury remains. The importance of the

Tilbury discovery lies in the fact that in size and form of head this individual may be accepted as a type which is still prevalent in the modern population of England. In 1862 Huxley distinguished a form of prehistoric English skull and gave to it the name "River-bed type." The specimens he selected to represent this type are in the collection of the Royal College of Surgeons, one being found in the alluvium of the Trent Valley, near Muskham, the other in a tumulus in Anglesey. The Tilbury skull also belongs to this type. Four other crania in the Museum of the College, found in circumstances which point to a great antiquity, are also of this type. A cranium of similar form was discovered by the Rev. E. H. Mullins, rector of Langwith-Bassett, Derbyshire, two years ago in a limestone cave, with remains of the reindeer and other forms of mammals now extinct in England. The cranium found in Gough's Cavern, Cheddar, was apparently also of this type, but the lecturer had not examined this specimen. The same type was found recently by Mr. Neil Baynes, F.S.A., in a tumulus of Anglesey, and it was evident from measurements made by Mr. Baynes on the heads of living inhabitants of that part of Wales that the River-bed type of man was still prevalent there. In the lecturer's opinion this ancient British type, in spite of many invasions, still formed the foundation of the modern population of England.

Professor Keith exhibited and described an almost complete skeleton of a man discovered last year by Mr. S. Hazzledine Warren, F.G.S., in a prehistoric (Neolithic) stratum which is being exposed by the sea on the coast of Essex, north of Walton-on-Naze. An antiquity of at least 4000 years can be assigned to this Englishman. He was a finely made young man, with a stature of 5 feet 2 inches, sharp prominent nose, finely moulded face, head, hands, and feet, and presented very distinct evidence of a specialisation in the right arm, pointing to a trade. His teeth were worn flat and met edge to edge as in pre-historic races. He evidently died in the autumn, for within the skeleton Mr. Warren detected over a pint of seeds of the blackberry and dog-rose, indicating the form of diet then available.

The lecturer also exhibited and described briefly the human remains which had lately been found during the systematic excavation of the rude stone monument at Coldrum, Kent. These excavations were carried out, with the permission of the Lord of the Manor, by Mr. F. J. Bennett, F.G.S., of West Malling, who has done so much to encourage archæological research in the central parts of Kent. Mr. Bennett found, during excavation of the stone chamber in the central part of the monument, remains of the skulls of ten individuals, with other bones, which included parts of about ten other persons, so that altogether apparently about a score of people had been buried there, many of them women and children. Unfortunately nothing was found during the excavation which permits a date or period to be assigned to the remains. If the remains found are the builders of the megalithic monuments of Kent, then these builders were people of medium stature, with heads in which the length was relatively great to the breadth. The metallic resonance of the bones found on the lower platform during the excavation points to a considerable antiquity for these remains. Further excavation by Mr. Bennett, which is much to be desired, may reveal more conclusive evidence as to the relationship between these people buried in the chamber and the builders of the monument.

---

SOUTH DEVON AND EAST CORNWALL HOSPITAL, PLYMOUTH.—The annual meeting of subscribers to the South Devon and East Cornwall Hospital was held on March 6th under the presidency of Mr. Waldorf Astor, M.P. The medical report stated that 1450 in-patients had been admitted during 1910. The out-patients numbered 2522. During the year 363 patients and 85 nurses were sent to the Pearn Convalescent Home, in connexion with the institution. The financial statement showed that the income amounted to £8519 and the expenditure to £10,004. The deficiency at the close of the year was £1485, compared with £2317 at the end of 1909. It was stated that in order to clear the deficit stock to the value of £5146 had been realised, but a legacy of £3000 had been received towards replacing that amount.

# "606" AND SYPHILIS:

## A REPLY TO MR. C. F. MARSHALL'S VIEWS.[1]

BY JAMES McINTOSH, M.D. ABERD.,
GROCERS' RESEARCH SCHOLAR;
AND
PAUL FILDES, M.B., B.C. CANTAB.
(*From the Bacteriological Laboratory of the London Hospital*—DR. W. BULLOCH.)

DURING the few weeks since "606" was put upon the market for general use an undertone of criticism has become manifest in this country. It is suggested that the claims of Ehrlich have not been substantiated, that the drug has been prematurely "boomed," and that it is rapidly finding its level as, at best, a useful auxiliary to mercurial treatment. These views found expression, to some extent tentatively, in a recent trade publication and led the reviewer of THE LANCET to detect therein a certain atmosphere of disappointment.[2] Some weeks ago Mr. Marshall, also, communicated a disparaging paragraph to a medical journal,[3] and after a similar note in another journal,[4] he has now found expression at some length as an original article in the columns of THE LANCET itself. Mr. Marshall arrives at the following conclusions:—

1. In the present state of our knowledge there is no drug which can replace mercury in the treatment of syphilis. 2. Although arseno-benzol causes rapid healing of certain syphilitic lesions, this effect is not constant and is often only temporary. 3. There is no proof that an abortive cure of syphilis can be realised by this drug. 4. If arseno-benzol is indicated at all in the treatment of syphilis, it is chiefly in those cases which are not influenced by mercury, but such cases are rare. Moreover, some cases resist the action of both drugs. 5. The administration of arseno-benzol is attended with many risks and dangers.

Up to the present no protest has appeared against what seems (to us) to be a totally unfounded chorus of disapproval. The matter might be considered to be one of no particular moment were it not for the fact that, in addition to misleading the great mass of the profession outside the vortex, as it were, of these questions, these expressions of disapproval directly reflect upon the veracity or scientific accuracy of those who have previously described the results of the use of "606." Among this latter class we find ourselves.

In April, 1910, Dr. W. Bulloch, bacteriologist to the London Hospital, obtained a supply of "606" from Professor Ehrlich. This material was entrusted to one of us and a series of experiments were carried out with it upon animals infected with syphilis and other diseases with a view to confirming the therapeutic and toxic effects. Some of these results were published in THE LANCET.[5] The complete justification of the claims of the drug in these respects led to its application to human beings on July 19th, 1910. From this date onwards "606" has been administered to a selection of hospital patients suffering from all forms and all degrees of syphilis. The administration has conformed to the repeated instructions of Ehrlich, and all cases have been in the beds of, and under the direct observation of, Dr. J. H. Sequeira, dermatologist to the London Hospital. Extensive and repeated observations have also been carried out in the Bacteriological Laboratory of the London Hospital. Special attention has been paid to the question of permanent cure or relapse, and thus a comparatively small number of cases only has been dealt with and followed. Only one case in our series has escaped continuous observation. We have had, therefore, eight months' experience of "606" on human beings; a similar period has been enjoyed only by a few who also obtained material from Ehrlich for use upon hospital patients. Mr. Marshall is not among these few. His personal experience must, therefore, rest upon any observations he may have made during the last few weeks, or conceivably upon a few cases he may have seen under treatment by the courtesy of others. These considerations lead us to believe that the results obtained at the London Hospital are of greater value than results, if any, obtained by Mr. Marshall.

[5] James McIntosh: THE LANCET, Sept. 3rd, 1910, p. 713.

Mr. Marshall probably is not acquainted with our cases, since our publication of them in THE LANCET[6] is now largely out of date; further, we believe that few other observers have as yet appeared in print. Thus, Mr. Marshall's opinions cannot rest upon published observations in this country, and it would have been more fitting if he had published his own evidence or waited for others to have completed their observations before embarking upon very wide conclusions which are entirely at variance with the enormous mass of publications to date, including those of the most celebrated syphilologists.

We propose to deal with Mr. Marshall's generalisations in some detail. At the outset he regrets the manner in which "606" has been introduced. He considers this manner commercial and not in accordance with the ethics of scientific medicine. Mr. Marshall is unaware of the despicable details surrounding this question; if he were, he would not have cast this slur upon the name of the greatest medical investigator of our time. We cannot go into details, but as a fact Ehrlich has distributed free vast quantities of "606" practically throughout the world. His institute was a Mecca for medical men coming from the most distant countries for "606." The place was crowded with personal applicants for "606." The Speyer House was a manufactory of "606" Does Mr. Marshall imagine that the great institute at Frankfort was to permanently lapse into a centre for distributing "606"? Is Behring's antitoxin still supplied free from the place of its origin? However, Mr. Marshall is annoyed that the manufacture has been handed over to a commercial firm. The manner of introduction of "606," however, should not be "naturally calculated to create a strong prejudice against it" when it has been vouched for by such eminent sponsors.

Mr. Marshall asserts that before "606" can replace mercury and iodides in the treatment of syphilis it must be proved capable of (1) aborting the disease, or (2) preventing tertiary or parasyphilitic manifestations, or (3) healing lesions more quickly, more constantly, and with less liability to relapse than is the case with mercury, or (4) it must exhibit fewer dangerous toxic effects. He says, "Let us see whether arsenobenzol has been *proved* [the italics are our own] to fulfil any of these conditions." By a series of remarkable generalisations, unsupported by adequate evidence, he finds that these conditions have not been fulfilled—*ergo*, "606" cannot replace mercury and iodides. He sets up a row of impossible essentials and then demolishes them. How can these things be *proved?* "606" has only been available for about 12 months and is still, in certain particulars, in the experimental stage. It is not *proof* which is looked for but reliable evidence, and this evidence must be obtained by experiment. We have amassed some evidence on these points, and this will be published when our experiments are sufficiently advanced.

Mr. Marshall's first demand relates to abortive cure, which, incidentally, is not what is meant by "*therapia sterilisans magna.*" We note his views on the Wassermann reaction and the perfectly obvious possibilities suggested by Flashman and Butler; we also note his remarks on superinfection, but these things were well known years before Pinard's Thesis of 1910. For our part we have evidence which justifies us in retaining the hope that an abortive cure of syphilis by "606" will be realised.

With regard to the second demand as to the prevention of tertiary and parasyphilitic lesions, we agree that this need not detain us. It is unusual, we believe, for such lesions to occur within two years of the infection, a period much longer than that during which "606" has been available. At any rate, we have not seen any records of these occurrences following a secondary attack cured by "606."

The question next arises as to whether "606" cures syphilitic lesions more rapidly or more constantly than mercury. Mr. Marshall refers to certain photographs. He says it is quite common for such results to be obtained by mercury. We, however, understand from the literature, and in particular from Dr. Sequeira, that such rapid healing as occurs with "606" is not common with mercury. With "606" these results are almost invariable. We have seen no syphilitic lesion, even of the gravest form, which has not healed with great rapidity after "606," except interstitial keratitis and three cases in which, after the syphilitic element had been removed, a second underlying pathological state was found. This is also the same conclusion of most, if not all, competent and apparently unbiassed observers. Relapses, as Mr. Marshall observes, have been reported. We may add that a large number of relapses have been reported; we also have had a large number. We have evidence that these relapses are dependent upon the size or method of application of the dose. Mr. Marshall labours under a singular delusion if he imagines that 0·6 gramme is an average dose. He cannot be aware of the repeated directions of Ehrlich to continually increase the severity of the application. 1·0 to 1·4 grammes of "606" may at present be taken as an average dose. We need hardly add that this amount is not given in one application, but in two or three fractions over a period of three to six days. One or two of these applications must be by the intravenous route. Ehrlich considers, and we follow him, that any much less intense treatment is merely trifling. The lesion may be cured, but many will relapse.

Next, Mr. Marshall states that "in fact" "606" treatment is merely symptomatic and does not touch the "disease itself"; he refers apparently to the spirochæte. Now, this statement of alleged fact is entirely erroneous. "606" has no reference to symptoms—it is purely a parasiticide, and further, by comparative experiments on man or animals, has repeatedly been proved to exert an enormously greater destructive effect than mercury in any form or any dose. In cases of chancre examined by us the organisms have not been detected in the lesion after about 14 hours in the case of intramuscular or subcutaneous injections, or nine hours in the case of intravenous. In animals we have seen a disappearance of spirochætes in seven hours after 0·1 gramme of "606," and in four days after two *human adult* doses of biniodide of mercury intravenously.

Lastly, Mr. Marshall refers to the dangers of "606." Several deaths have occurred; we believe that the number must now reach about 20 or more. Some of these were advanced cases of general paralysis. The result is not surprising. About six also were infants. Death was hastened in these cases during the period of determination of a suitable dose for such infants. These accidents should not occur at the present time. Other deaths have occurred in subjects of organic heart disease or vascular degeneration. Ehrlich has repeatedly urged that such patients should be treated with the greatest care. These deaths are due to a relatively too intense treatment and not necessarily to any particular form of application. Mr. Marshall's statement that the intravenous route is particularly dangerous is not borne out by facts. We call to mind one death only which was directly attributable to this method—a case of embolism of the pulmonary artery. The cause of this embolism was explained and must be guarded against. Alarming symptoms have also arisen from neglect of obvious precautions or distinct recommendations. All these things are to be found in the literature. For our part we have not yet seen any occurrence following an intravenous injection, which would give anyone the slightest alarm, nor, of course, after any other form of application.

Among the possible remoter ill-effects is blindness. Blindness due to optic atrophy after the use of arsenical compounds is notorious, and was a potent factor in inducing Ehrlich to restrict the use of "606" until the occurrence of these accidents could be excluded. They have been excluded; they have not occurred. Relative blindness, however, may occur, but these cases have no direct connexion with "606." They are pure relapses, syphilitic iritis or retinitis, and are no more frequent than, and do not differ from, the inflammatory eye lesions occurring with or without mercury treatment. We have ourselves observed a case.

To sum up, we find that on the evidence the criticisms of Mr. Marshall are unjustified and at variance with the opinions of the vast majority of competent observers. The conclusions relating to "606" which we feel justified in arriving at are:—

1. On the average, if not invariably, "606" is far superior to mercury in the symptomatic treatment of syphilis.

2. It is certain in the earlier stages of syphilis, and probable in the later, that courses of "606," applied at properly ascertained times, will prevent the onset of symptoms with far less inconvenience and effect upon the general health than mercury.

3. "606" will probably be used by the unskilled as

[6] James McIntosh and Paul Fildes: THE LANCET, Dec. 10th, 1910, p. 1684.

subcutaneous or intramuscular injections for the symptomatic treatment of syphilis without danger.

4. The skilled will use intravenous injections in the hope, not without foundation, of realising a *therapia sterilisans magna*.

## OBSERVATIONS ON THE USE OF SALVARSAN IN SYPHILIS.

BY T. W. GIBBARD, M.B. DURH., M.R.C.S. ENG.,
MAJOR, ROYAL ARMY MEDICAL CORPS; IN CHARGE, MILITARY HOSPITAL, ROCHESTER-ROW, S.W.; LECTURER IN SYPHILOLOGY, ROYAL ARMY MEDICAL COLLEGE;
AND
L. W. HARRISON, M.B., CH.B. GLASG.,
CAPTAIN, ROYAL ARMY MEDICAL CORPS; PATHOLOGIST, MILITARY HOSPITAL, ROCHESTER-ROW, S.W.

IN the course of an investigation into the value of Ehrlich's latest remedy for syphilis, which we have been carrying out at the Military Hospital, Rochester-row, for some months now, some points have occurred which may be of general interest.

Realising its enormous importance to the army should the claims for the effect of "606" on syphilis which were at first advanced be substantiated, we determined to carry out as thorough an investigation as possible for ourselves, and in June last year applied to Herr Geheimrat Professor Ehrlich for some samples of his remedy. Professor Ehrlich very kindly placed a generous supply at our disposal, and we should like to take this opportunity of expressing our appreciation of his kindness in renewing our supply from time to time till the remedy was placed on the market, as well as for his courtesy in answering the inquiries on various points which we addressed to him.

For the purposes of our investigation we have taken into consideration (1) the method of administration, with dosage; (2) the immediate after-effects attendant on each method of administration; (3) the effect of the remedy on (*a*) the clinical signs of the disease, (*b*) the treponemata present in local lesions, (*c*) the Wassermann reaction; and (4) the question of relapses.

Our inquiry has so far been carried out on 150 cases of syphilis, and these, with the exception of a very small proportion which has passed out of our control by transfer to the Army Reserve, will continue under observation till the investigation is closed.

In regard to methods of preparing the remedy for use, we have experience of three, two for subcutaneous or intramuscular injection, and one for intravenous. The first we adopted was that advocated by Michaelis; it was chosen because it resulted in a more nearly isotonic emulsion than others, and was as follows: 20–30 c.c. of hot, sterile, distilled water were poured into a porcelain capsule, and into it was slowly sprinkled the dose of "606" it was intended to administer, the solution being stirred vigorously meantime. To the highly acid yellow solution which resulted normal NaOH solution was added in the proportion of 1 c.c. of the alkali to every decigramme of the salt, the mixture being constantly stirred. The result was the formation of a flocculent precipitate which finally dissolved, leaving a clear, yellow, highly alkaline solution. To this was added three drops of 0·5 per cent. alcoholic solution of phenolphthalein, which turned it crimson. Normal acetic acid was then added drop by drop till the crimson colour disappeared, indicating neutrality. Meantime a golden yellow precipitate formed, so that finally the capsule contained a yellow emulsion, which was made up to 40 c.c. by adding sterile physiological salt solution. In later cases we discarded the use of phenolphthalein as an indicator and used litmus paper, to which the emulsion was made slightly alkaline.

The emulsion was injected deeply into the subcutaneous tissues between the angles of the scapulæ, 20 c.c. on each side, in the earlier cases, and later into the deep subcutaneous tissues overlying the pectoral muscles or into the muscles themselves. The injection was made very slowly, avoiding the immediate neighbourhood of the skin, and the resulting tumours were dispersed by massage.

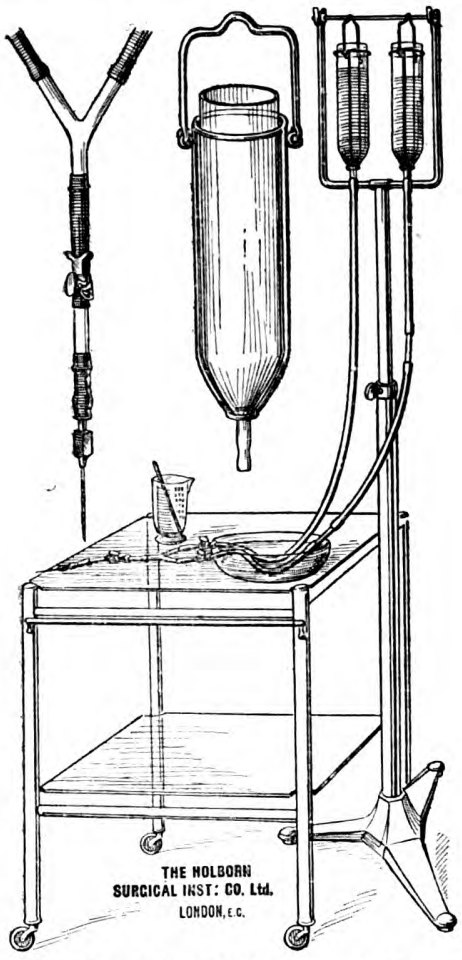
In order to avoid the inconvenience of administering such a large volume of emulsion by injection, after injecting 38 cases by Michaelis' method, we changed our technique to that advocated by Wechselmann and Lange, and prepared the emulsion as follows. The salt was poured into a porcelain vessel and dissolved by rubbing it up with ordinary caustic soda solution. Glacial acetic acid was then added till the golden yellow emulsion which resulted was only slightly alkaline to litmus paper. The precipitate was then taken up into 8–10 c.c. of sterile physiological salt solution and injected as above.

The immediate effect of an injection given in either of the above ways was some local pain, which varied in intensity with different patients from very slight to somewhat severe, but generally disappeared in an hour or two. The following day, or the day after, a local reaction, accompanied by pain and swelling, occurred at the site of injection, the pain being sufficiently severe in a few cases to require a small dose of morphia. This reaction lasted for a variable time, but in the great majority of cases had died away by the sixth day. The temperature on the evening of injection exceeded 100° F. in only 7 out of 43 cases, the highest recorded being 103·4° F., and the next highest 102° F. On the second, third, and fourth evenings the temperature was on the whole higher, though in no case did it rise above 102·2° F. Patients varied considerably as to the day on which their subsequent fever was greatest, but in the majority it attained its height on the third evening. On account of the local reaction and fever, it was found necessary to keep almost all the cases in bed for five days.

We have found that a great disadvantage of this method of administration is, besides the pain and discomfort, the local infiltration at the site of injection, and the risk of the skin sloughing, especially if the injection is made subcutaneously. We believe that in every case where "606" is given in this way there is necrosis of tissue at the site of injection, however deeply placed the latter may be, and in this we are supported by Orth, who showed to the Königsberg Conference two specimens of necrosis in gluteal muscles which had given no clinical evidence of their presence during the six weeks which elapsed in each case between the injection of "606" and the death of the patient. In a few of our cases the skin sloughed at the end of from 10 to 14 days, while in five others a slough formed at the end of from three to four months. Some of the sloughs, which consisted of necrosed muscle, skin, and subcutaneous tissue, were analysed by Major W. W. O. Beveridge, R.A.M.C., at the Royal Army Medical College, and all of them, including those which formed from three to four months after the injection, were found to contain arsenic, some in surprisingly large quantities: thus, after an injection of 0·4 grm., an amount of arsenic equivalent to 0·075 grm. of "606" was found in one slough four months later. In view of this fact, it seems to us probable that only a very small proportion of the remedy administered in this way can be absorbed daily into the circulation, so that if it is possible to produce "606"-resistant strains of treponemata by administering minute non-lethal doses of the drug to them this would appear to be a good way of doing it. In many of our cases the friction of accoutrements caused local infiltrates to form, and these sometimes necessitated the soldier being excused part of his military duty for a few weeks, though none of the patients had been returned to duty in less than a fortnight after the injection, or before all local trouble had apparently subsided. On these grounds we were glad to adopt Professor Ehrlich's advice to use the intravenous method. In preparing the drug for administration in this way we have been guided by Dr. Schreiber's papers on the subject, and do so as follows: Into a glass cylinder, graduated in cubic centimetres, are poured 100 c.c. of hot, sterile, distilled water, and the contents of a capsule of salvarsan are slowly shaken into it, while the mixture is vigorously stirred with a glass rod. To the resulting clear yellow solution normal NaOH solution is then added from a pipette while stirring. A flocculent precipitate forms at first, which re-dissolves, leaving a clear yellow, alkaline solution. When quite clear the solution is made up to 200 c.c., with warm, sterile, physiological salt solution, and is then ready for use. If it be desired to give a smaller dose than is contained in one capsule (0·6 grm.), it is convenient to make the final quantity of solution 240 c.c., so that each 40 c.c. of it corresponds exactly to 1 decigramme of the powder, and the dose can be accurately gauged. The important point about this method of making up the solution for injection is

its great dilution, since to administer "606" intravenously in a concentrated solution is highly dangerous. Having prepared the solution, the vessel containing it should stand in hot water while the apparatus for injecting it is being arranged. This applies also to the salt solution when not in use.

The intravenous administration of "606" consists briefly in puncturing a prominent vein with a suitable hollow needle, allowing a little salt solution to flow into the vein through the needle to make sure that the latter is really inside the vessel, following this up with the amount of "606" solution it is desired to administer; and, finally, running in more saline to clear the needle and its immediate neighbourhood in the vessel of all traces of the remedy. To carry this out we have used various forms of apparatus, including the special syringe invented by Dr. Schreiber, but our present one is simply an elaboration of the old funnel, rubber tubing, and hollow needle which have been used for transfusion purposes for very many years. We still use the latter simple form of apparatus, which Dr. H. W. Bayly[1] saw when he visited us early in December last, on occasions when it is inconvenient to arrange for a stand, but have modified it



for injections given in hospital, because we find that time is saved by having the salt solution and remedy in separate containers, provided the latter can be suspended from a stand. We note that we have quite independently adopted an arrangement which resembles in some particulars that designed by Dr. O. F. F. Grünbaum.

Two glass containers, each to hold 300 c.c., and shaped like the barrel of an ordinary glass syringe, have 4 feet of rubber tubing attached to each, that leading from one container being interrupted by two short pieces of glass tubing which act as windows (see illustration). Into the other end of each rubber tube is inserted one arm of a glass Y-piece. To the stem of the Y-piece is attached another piece of rubber tubing about 6 inches long and also provided with a glass window, and to the other end of this short piece of tubing is fitted a connexion to take the needle. The latter has a calibre a little greater than that of an ordinary hypodermic syringe, from which it differs in having a shorter point, so that there may be no risk of the latter wounding the other side of the vein by any slight movement of the needle while the injection is being given. Each of the three pieces of rubber tubing mentioned is provided with a spring clip so that the flow of fluid through it can be started or shut off at any desired moment. Previously to being used the container, rubber tubing, &c., are sterilised by boiling or autoclaving, and the needle by keeping it stored in spirit.

The apparatus is worked as follows: The containers having been suspended on a convenient stand which is capable of being raised, the two clips on the tubes between the Y-piece and the containers a e opened, while that on the tubing leading from the Y-piece to the needle is closed. Warm, sterile, physiological salt solution is then poured into one of the containers and finds its own level, *viâ* the Y-piece, in the other. In doing so, it imprisons many air bubbles which must be worked out of the tubes by manipulation. Having removed all air bubbles, and with the level of the salt solution standing about an inch from the bottom of each container, the clip is applied to that tube (leading from one of the two containers) which has the glass windows inserted so as to occlude it, and the quantity of "606" solution it is desired to administer is poured into the corresponding container. The other container is filled with warm physiological salt solution. The needle is then attached and the clip on the tube between it and the Y-piece opened so as to allow some salt solution to flow from the last mentioned container through the needle and remove air. This accomplished, the clip is again applied between the needle and Y-piece, and all slack tubing coiled into a shallow vessel containing water at about 110° F., so that the solutions may be warmed as they flow through. Depending on the rate of flow, each particle of solution remains in the rubber tubing for one and a half to two minutes, and, being there exposed to a large cooling surface, it is desirable to warm it just before it reaches the needle.

The patient being in bed, or on an operating table, with the arm supported in a comfortable position, a prominent vein at the bend of the elbow is selected, and the skin over it painted with a solution of iodine in chloroform (1 in 15) to disinfect the operation area. A rubber band is then applied to the upper arm so as to retard the venous return, without abolishing the radial pulse, and the patient made to clench and unclench his fist a few times to make the selected vein stand out well. A little care to distend the vein well in this way sometimes repays trouble, because the shape of the needle-point, though an advantage for reasons already given, does not lend itself to easy penetration of the vein, and if the latter be little supported by surrounding tissues, and half filled, it is apt to slip to one side before the needle. With the needle pointing in the direction of the blood flow, almost parallel with the skin surface, and its eye looking upwards, its point is applied to the skin well over the centre of the vein and pushed steadily on into the vessel. It is better to perform this trivial operation steadily than with a quick movement, such as one can adopt with the ordinary long-pointed needle frequently used for bleeding purposes, because the vein is then less likely to slip to one side or the needle to perforate the other side of it. It must rarely be necessary to expose the vein with a scalpel, since in 186 administrations by this method we have been compelled to do so only once, in a very stout patient. Even in this case we think now that had we taken a little more care to distend a vein well it would not have been necessary, since this patient received a second injection, and the vein was then entered without the use of a scalpel. With experience one knows by touch when the vein has been successfully penetrated, but if it be desired to ascertain this more certainly the containers are previously lowered to a level a little above that of the patient. The appearance of blood at the window between the needle and the Y-piece when the corresponding clip is opened will then confirm one's tactile impression. The containers are then raised, the rubber band on the upper arm removed, and, both clips between the salt solution container

[1] THE LANCET, Jan. 21st, 1911, p. 153.

and the needle being already open, salt solution will commence to flow into the vein. Here, again, it will be noticed that although the salt solution is flowing no swelling happens over the vein such as would occur if the needle were not properly inside the vessel. A little salt solution (about 10 c.c.) having been allowed to flow in this way, the clip on the tube leading from the salt solution container is closed and that on the tube leading from the "606" container opened, when the remedy will commence to flow steadily into the vein. When it has nearly reached the bottom of the container about 20 c.c. of salt solution are poured in so as to help the last few cubic centimetres of "606" solution along the rubber tube. Finally, when the level of the fluid passes the upper glass window the container is raised to increase the pressure, and when the fluid passes the lower window the clip is applied, while that on the tube leading from the salt solution container is opened so as to allow salt solution to wash the needle and the vein wall immediately adjacent free from "606." This done, the needle is removed and a dressing applied.

We can only add that in actual practice the whole operation is not nearly so complicated as would appear from our description. In fact, it is quite usual with us to administer salvarsan in this way to five patients in an hour. The rate of flow of the solution into the vein can be regulated by the height to which the containers are raised. As a rule, about 30 c.c. per minute can be safely given, but some patients cannot deal with this amount in the time and complain of oppression. In such cases the rate is easily moderated, of course, by lowering the containers.

We prefer the transfusion method to the use of a syringe because it is simpler; any part of the apparatus can be improvised from material which is readily obtainable, and this is an advantage, considering that no glassware is immune to breakage. In addition, it is easier to keep the needle in position; in fact, if the rubber tubing between the needle and Y-piece be lightly fastened to the arm with a piece of strapping one need not hold the needle at all while the solution is running into the vein. The advantage of having two containers arranged in this way is that the needle can be washed completely free of salvarsan solution before it is removed from the vein.

The immediate after-effects of an intravenous injection are generally as follows. In a very few cases some nausea, and possibly vomiting, occurs at once, but in the great majority no symptoms make their appearance till from two to three hours later, when in about 50 per cent. of cases there is a feeling of chilliness, which may go on to a rigor lasting an hour or so, and the temperature rises. In our cases of this kind the temperature varied from 100° to 103·2° F., with an average of 102°. In the great majority of our cases any nausea and vomiting which occurred were slight, and all after-effects had disappeared by the next day, but in five there were persistent vomiting and diarrhœa which lasted well into the following day. In two cases vomiting was preceded by faintness which appeared alarming, the pulse being almost imperceptible and the pallor extreme, but these symptoms rapidly passed away after the patients had vomited; each of these patients was in a very debilitated condition. Previous preparation of the patient seems to influence these after-effects, and we advise a saline purge in the morning, restricted fluids, and no solid food for two to three hours previously. For 24 hours subsequently to the injection a very light diet is advisable. On the second day the temperature has been over 100° five times out of the 186 occasions on which we have given salvarsan intravenously, and three times on the evening of the third day, the highest temperature then recorded being 101·4° in one case. The urine was examined in every case on the day following the injection and slight albumin found twice only, and in one the patient had a urethral chancre. Both cleared in a few days. In one of our cases thrombosis of the vein occurred, but caused no inconvenience, and had disappeared a fortnight later. In another case some swelling of the arm developed a few days after the injection. This was probably due to the needle having punctured the deep side of the vein by some accidental movement during the latter part of the injection. The infiltrate subsided in about ten days without having given the patient any inconvenience. With these exceptions we have experienced no local trouble through the intravenous method.

Regarding dosage, in the subcutaneous or intramuscular cases the largest dose we administered was 0·8 grm., the smallest, 0·4 grm., and the usual one, 0·6 grm. For intravenous injection, in ordinary cases of syphilis in men without nerve or visceral complications, we have usually given from 0·5–0·6 grm., according to weight and physical condition, while in cerebral or spinal cases, or in those suffering from marked cachexia, the usual dose has been from 0·2 to 0·4 grm. In our first series of intravenous cases we gave a single injection; in the next series, two injections of the above-mentioned dose at an interval of from two to three weeks; and we have recently commenced a series in which the above initial dose is given, and this is followed, at intervals of two weeks, by three injections of 0·2 grm. each, the object being to prolong the effect over a greater period of time. In framing this programme we have been influenced by certain considerations connected with the excretion of salvarsan after intravenous injection and the possible relation of this to relapses.

Major Beveridge has estimated the daily excretion of arsenic by the kidneys in a number of our cases after intravenous injection, and has found that after a dose of 0·55 grm. the urine becomes free from arsenic in an average of nine days, and, according to present knowledge, this seems the limit of time during which we can rely on the presence of the remedy in the circulation for destruction of treponemata. Relapses after "606" may be due to various causes, the relative importance of which we know very little. Amongst others the following occur to us as worthy of consideration. 1. Amongst the multitudes of treponemata originally infesting the patient, some are resistant to this remedy from the first, and, surviving the injection, procreate a fresh invading host of parasites. 2. Some, being assailed by a dose insufficient to kill them, become resistant. 3. Possibly there is a stage in the life-history of T. pallidum in which it is always "606" resistant; in this case all parasites which happened to be in this stage of development during the presence of the remedy in the circulation would escape extermination. 4. Many may lie protected in thrombi or in parenchymatous cells, and only escape from these later after all the remedy has been excreted. In the absence of light on this question we can only seek the best method of administration on a principle of trial and error, in the hope that one or both of the two last possibilities we have mentioned explain the majority of relapses, and that permanent cure is only a question of ensuring the presence of the remedy in the circulation for a given length of time. Considering the very rapid clinical effects which occurred after the first injection in those of our cases which developed a slough three to four months later, and the large amount of arsenic found at the site of injection at the end of this period, granting that the clinical effects were due to the wholesale destruction of T. pallida, it seems probable that it requires the presence of a very small dose of salvarsan in the circulation to destroy all the treponemata reached by the blood stream, and it is on this principle that we have framed the programme for our latest series of cases.

We have gone into this matter of administration in some detail because it seems to us as unjustifiable to attack this remedy on the score of relapses, before the best method of using it has been discovered, as to have denied the efficacy of quinine in malaria because recrudescences of fever occurred more frequently before its administration was properly understood.

Regarding the effect of salvarsan on the various manifestations of syphilis, the following extracts from our notes may be interesting. In order to compare the effect of the remedy on the separate lesions of syphilis we have noted the time which has elapsed between the injection and the disappearance of each. In 35 cases with primary sore the latter healed completely in an average of 10·5 days each. In 15 of these no secondary symptoms had appeared when the injection was given, and none have yet developed secondaries, though in 13 a period varying from six weeks to five months has elapsed since the injection. In 45 cases which showed secondary ulceration of mouth and throat the lesions had completely disappeared in an average of 8·8 days. Five cases of roseola cleared completely in an average of 10·4 days, 15 of macular rash in an average of 7 days, 11 of papular rash in an average of 6·3 days, 3 of pustular rash in an average of 12 days, and 6 of condyloma in an average of 9 days each. With the exception of the local

treatment to primary sores mentioned below none of these cases received any other treatment whatever.

In all cases of primary sore or condyloma T. pallida were found in great numbers previously, but in none later than 48 hours after injection. Out of 97 patients suffering from the above lesions 7 have relapsed since the injection. In three of these a primary sore was the only lesion, and this has recurred: in one, two months after a subcutaneous injection of 0·6 grm.; in one, 10 weeks after a single intravenous injection of 0·5 grm.; and in the third, 10 weeks after the first of two intravenous injections of 0·5 grm. On account of these relapses we now make it a practice to treat each primary sore locally by excision, cautery, or 30 per cent. calomel ointment, on the principle that many parasites in it may be protected from attack, viâ the circulation, by reason of being embedded in thrombosed vessels. Of the four remaining cases, one had ulceration of the throat, and this recurred three months after a subcutaneous injection of 0·6 grm.; the second originally suffered from ulceration of the tongue, which recurred 10 weeks after a subcutaneous injection of the same dose; the third had ulcerated throat and roseola, both of which recurred four months after a subcutaneous injection of 0·6 grm. into two sites, one of which sloughed; the fourth had ulcerated throat, roseola, and synovitis of the left elbow, all of which reappeared three months after a single intravenous injection of 0·5 grm. Two of these cases had been previously treated by injections of atoxylate of mercury. The above include all the relapses which have so far occurred in our cases, with one exception mentioned later. Four of these relapses were treated with a second injection, and in three the symptoms cleared completely in four to eight days.

In one case of general paralysis with marked delusions an intravenous injection of 0·2 grm., followed by a subcutaneous one of the same dose, caused no improvement; in another case which was less advanced, the patient showed marked improvement in speech after two intravenous injections of 0·2 and 0·4 grm. given at an interval of two weeks, but it is much too early to pronounce definitely on the result. In an advanced case of tabes, with optic atrophy and paraplegia, 0·2 grm. given intravenously failed to improve the eye symptoms, but the injection was followed by distinctly increased power in the legs. In a case of tabes with well-marked signs, some improvement occurred after an intravenous injection of 0·2 grm., so that the patient could walk upstairs with less difficulty and stand for about 30 seconds with eyes closed and feet together. The improvement was only temporary, however, and all the symptoms returned with their original severity. In a very early case of tabes with Argyll Robertson pupil and lightning pains only, the pupil was unaffected and the pains not entirely abolished by two intravenous injections of 0·3 and 0·5 grm. respectively. These are all the cases of parasyphilis we have treated.

In order to test the remedy in cases where mercurial treatment had failed to arrest troublesome or dangerous symptoms, or to prevent frequent recrudescences of the disease, or was badly tolerated, the Director-General, Army Medical Service, invited the medical officer in charge of each military hospital in the United Kingdom to send particulars of such cases, with a view to their transfer to the Military Hospital, Rochester-row, for treatment with salvarsan, and in this way we have had an opportunity of treating 10 cases in which mercury failed to produce any impression, though administered regularly from a very early stage; 22 where the same regular treatment had failed to prevent frequent relapses; 1 in which it failed to produce any impression when mutilating ulceration had well advanced; and 1 which could not tolerate mercury. In all of these cases, with one exception, the injection of salvarsan was followed by the complete disappearance of all active signs of the disease. The exception was a case of ulceration of the larynx and hard palate, with necrosis of bone. The ulceration has completely healed, but the patient's voice is still rather hoarse.

The following brief extracts from the notes on some of our cases may be interesting:—

CASE 1.—Private —— contracted syphilis in June, 1910, and on July 20th developed mild syphilitic iritis of left eye, which cleared up under injections of calomel cream. Weekly injections of mercurial cream continued till August 23rd. On August 16th slight relapse of iritis and mucous patch on the left tonsil. Iritis had disappeared by August 20th, but the patch on the tonsil had become much worse. On Sept. 5th severe relapse of the iritis, which was much worse than on any previous occasion. He was given an intramuscular injection of calomel gr. ½. On Sept. 7th his condition was as follows: Vision of the left eye reduced to hand movements, two large deposits on iris, firm posterior synechiæ, and much lymph on posterior surface of cornea. Vision of right eye, 6/12. Injection of 0·6 grm. "606" subcutaneously. Sept. 8th, severe local reaction in eye, which was much congested and so painful that an injection of morphia was required. Three days after injection nodules on the iris distinctly smaller; counted fingers at 3 feet with left eye. Twenty-six days after injection vision in each eye was 6/12, and he could read D. 6 at 18 inches. Synechiæ remain. No return of eye symptoms up to March 14th, 1911. The mucous patch disappeared in four days after injection. No mercury administered since injection of salvarsan.

**In this case the injection of calomel cream given two days previously to that of "606" possibly obscures the issue, but, without wishing to lay too much stress on the effect of salvarsan in this case, it must be remembered that the two relapses of iritis occurred while the patient was fully under the influence of mercury.**

CASE 2.—Gunner —— acquired syphilis in June, 1906. Readmitted in December, 1906, for severe ulceration of the throat; two further admissions for relapses between then and August 28th, 1910, when severe iritis commenced, for which he was in hospital for 108 days. At the end of this time he was transferred to Rochester Row for treatment with "606." His previous treatment had included 49½ grains of mercury by intramuscular injection, with variations in the form of hydrarg. perchlor. and hydrarg. c. cret. and potassium iodide by the mouth. His condition on transfer was as follows: Right eye, vision = 6/60, iris irregular, with firm posterior synechiæ; fundus not visible on account of numerous deposits scattered on the posterior surface of the cornea. Left eye, vision = 6/18, otherwise normal. Injection of 0·5 grm. salvarsan intravenously, followed by no reaction. Injection followed by slight improvement. On Dec. 30th, second injection of 0·5 grm. intravenously, followed by severe reaction. One week later, vision of the right eye = 6/24 (2); less lymph on posterior surface of the cornea so that optic disc and retinal vessels seen; no optic neuritis or choroiditis; synechiæ remain. On Jan. 9th, 1911 discharged from hospital with vision of the right eye, 6/18 (2), and reads D = 3. No recurrence up to date. Wassermann reaction, strongly positive on admission, had become ± by day of discharge; blood not received since for further tests.

CASE 3.—Gunner —— contracted syphilis in September, 1908. Treated with regular courses of mercury by intramuscular injection, with intervals of rest, from then till August, 1910, receiving 38 gr. of mercury. In August, 1910, he developed a large indolent ulcer on the left thigh, and on Nov. 28th was admitted to R. Herbert Hospital, Woolwich, for gummatous ulceration of the soft palate and left tonsil. Mercurial injections continued, with potassium iodide by the mouth, with little or no improvement, and mercury had to be stopped on account of symptoms of salivation. Transferred to Rochester Row for treatment with "606," when examination showed large perforating ulcer of the soft palate, embracing part of the left posterior pillar of the fauces and tonsil. Intravenous injection of 0·5 grm. salvarsan. Two days later throat very distinctly better. On Dec. 22nd, 1910, second injection of 0·4 grm. intravenously. Small ulcer still present on the left tonsil, but clean and rapidly healing. On Jan. 14th, 1911, no active signs of syphilis. No recurrence up to Feb. 28th.

CASE 4.—Private —— contracted syphilis in May, 1909. Regular treatment with mercury by injections, as well as at other times by the mouth, from June, 1909, when first admitted for severe ulceration of throat, which healed very slowly under treatment. Spent 440 days in hospital between June, 1909, and October, 1910, having been readmitted seven times for ulceration of the throat. Last admission August 2nd, 1910. In spite of careful local and mercurial treatment throat became steadily worse till Nov. 12th, 1910, when he was reported as "seriously ill." On Nov. 18th feeding by the tube was commenced and continued for a few days. Slow improvement from then to January, 1911, when he was transferred to Rochester Row for salvarsan treatment. His condition then was as follows: The patient was very thin and feeble; very extensive ulceration of the pharynx and epiglottis; voice very indistinct, but the condition of the larynx could not be ascertained on account of much frothy mucus obscuring view. On Jan. 4th intravenous injection of 0·5 grm. salvarsan. Preparations were previously made for tracheotomy should a local reaction at the site of manifestation of the disease, such as sometimes occurs after injection of this remedy, cause œdema glottidis. Injection was followed by severe nausea, faintness, and vomiting, after which he revived. The temperature rose to 100° F. on the day of the injection, and was 102° on the third evening, subsequently being normal. Improvement very rapid from the fifth day after injection. Second injection of 0·55 grm. given intravenously on Jan. 17th and followed by no reaction. Ulcers had completely healed by the eighteenth day after the first injection, and he was discharged hospital on Feb. 3rd with no active signs of syphilis and having gained 18 lb. in weight in 34 days. Wassermann reaction still positive on the day of discharge; no subsequent test has been made as patient (Reservist) has gone to his home.

CASE 5.—Pensioner —— contracted syphilis early in 1900 and was treated by the mouth till secondary symptoms had disappeared. At this time the systematic treatment of syphilis, under which a patient once infected is not lost sight of till pronounced cured or he leaves the service, had not been introduced into the army, and on transfer to another station further treatment depended on the outbreak of fresh symptoms. In this case no further symptoms occurred till April, 1910, when he was admitted to hospital for ulceration of the head, face, and other parts of the body, the number of ulcers being 40. Under treatment with mercury and potassium iodide by the mouth some of the ulcers on the face had commenced to heal by November, but at this time a fresh crop of ulcers had broken out elsewhere, and he was rapidly going downhill. When transferred to Rochester Row on Nov. 24th his condition was as follows: His face was covered with large ulcers; there was complete destruction of a portion of the right side of the nose, with very offensive nasal discharge; large ulcers of the scalp and both sides of the neck; perforating ulcer of the sole of the left foot, and a very large, deep, and offensive ulcer, 3½ inches across, on the inner side of the left ankle; minor ulcers on other parts of the body. Patient very thin and so deaf that he could only hear when shouted at. Intravenous injection of 0·5 grm. salvarsan. One week later the ulcers

on the neck and nose had completely healed and hearing was normal. On Dec. 20th a second injection of salvarsan (0·4 grm.) was given intravenously. On Dec. 31st ulcer on ankle ¼ × ⅜ inch; weight 11 st., a gain of 3½ lb. Discharged hospital with all ulcers completely healed and feeling quite well on Feb. 11th. Wassermann reaction, strongly positive on transfer, completely negative three weeks later and also negative on the day of discharge.

**In this case mercurial treatment did not have a fair trial in the early stages of the disease, but after April, 1910, it failed in the hands of a very experienced officer, where salvarsan succeeded in arresting the progress of lesions which could otherwise have only ended with the death of the patient.**

CASE 6.—Private —— contracted syphilis in October, 1910. Treatment commenced with three injections of calomel cream (gr. ⅔ each), followed by injections of mercurial cream (mercury gr. 1 in each) at weekly intervals. After two of the latter had been given severe ulceration of pharynx, with secondary rash, occurred, and albumin was noted in the urine. One more injection of mercurial cream (mercury gr. ½) was given and its effect on the amount of albumin carefully noted. Albumin markedly increased on the day after the injection, and mercurial treatment was temporarily suspended. Œdema of the face and ankles followed, with diminished urine and greatly increased albumin, while ulceration of the pharynx became very severe. General measures for nephritis having failed to cause any improvement, and an injection of mercury salicylate, gr. 1½, having been followed by some aggravation of the symptoms, 0·5 grm. salvarsan was given intravenously on Jan. 23rd, 1911. The following day there was no albumin in the urine; on the third and fourth days albumin was very slight, and since then a very slight amount of albumin has been found every third or fourth day, its presence being indicated by a slight haze on boiling. The urine has increased in amount and the œdema entirely disappeared. The throat commenced to heal from the second day, and by the time a second injection of 0·5 grm. was given intravenously, 14 days later, there was no clinical evidence of syphilis. Wassermann reaction, strongly positive on the day of the first injection, was still positive on the fourteenth day, but completely negative four weeks after the first injection.

TABLE I.—*Wassermann Reactions before and after Subcutaneous Injection of Salvarsan.*

| | As tested by the original method. | | | | | | | | As tested by Stern's modification. | | | | | | | |

CASE 7.—Private —— contracted syphilis early in 1907 and treated with seven courses of mercury cream by intramuscular injection, receiving 40 grains of mercury in this way, two courses of soamin, gr. 50 each, and two of mercury atoxylate, gr. 10½ each, as well as inunctions of mercury at various times. Throughout treatment there was constant recurrence of syphilitic lesions, chiefly affecting the mouth. On Oct. 8th, 1910, admitted with tongue fissured and ulcerated, and mucous patches on the buccal mucous membrane. On Oct. 10th he was given an intramuscular injection of salvarsan (0·6 grm.), which was followed by severe local reaction, and a slough formed at one of the two sites of injection 12 days later. Improvement in the mouth and tongue commenced from the third day, and on Nov. 12th no signs of syphilis were apparent. No recurrence up to Feb. 28th, 1911, but Wassermann reaction still strongly positive.

CASE 8.—In an early case of syphilis which developed anterior poliomyelitis, with paralysis of muscles of both legs, wasting and reaction of degeneration of extensor group, all of which took one month to develop, the patient was able to litt his legs easily from the bed three days after an intravenous injection of 0·4 grm., and six weeks later could walk without the aid of a stick, though the extensors of the right leg were still very weak and there was no return of the patellar reflex. In this case the improvement continued till three months after the injection, when he suddenly developed paresis of the tongue, chiefly affecting the right side, so that he could not protrude it; there was also some paresis of the right external rectus, and his manner became curious. These symptoms passed off in two days with the exception of the mental ones. Space will not allow us to describe this interesting case more completely, and he is only mentioned here to complete our list of relapses.

One of us (L. W. H.) has tested the blood of our cases before the first injection and, as far as possible, at regular intervals after, and the results of the 883 reactions obtained are shown on the accompanying tables, in which the results obtained after each method of administration are shown separately. The results of the test for the Wassermann reaction which different observers have obtained after the injection of "606" have varied very widely, one worker showing 100 per cent. of negatives, and another only 25 per cent. Possibly the differences are explained by the different techniques adopted, and it seems desirable that in all cases some particulars of this should be stated. In explanation of the attached tables, the tests were conducted by the original method as well as by Stern's modification, which, as will be seen from the results, is more delicate than the original. The "antigen" used was an alcoholic extract of syphilitic infant's liver, which deviates 0·1 c.c. complement when in a combination of 0·03 c.c. extract and 0·2. c.c. inactivated serum of a florid syphilitic. It was used in a strength of 0·2 c.c. for the original and 0·03 c.c. and 0·06 c.c. for the Stern test. The patient's serum was inactivated by heating a small quantity (0·4 c.c.) of it at 55° C. for ten minutes only, as this has been found to result in a much more delicate test than when the serum is heated for the usual half hour. To form an estimate of the strength of the reaction in the case of each test two quantities of complement, 0·1 c.c. and 0·2 c.c., were used in the case of the original and two quantities of extract in that of Stern's modification. Deviation of 0·2 c.c. complement in the case of the original and with 0·03 c.c. extract in the case of the Stern test were counted as the stronger reactions. In the accompanying tables the numbers of sera which showed a weaker reaction after treatment with "606" are shown in a separate column under each test and are made up of those which, in the case of the original, deviated the stronger amount of complement before the injection and subsequently the weaker amount only, or at first deviated only the smaller amount and subsequently became ±. In the case of the Stern test those which at first showed deviation with the smaller amount of extract and subsequently deviated with the larger amount only are included in this category. It will be noted that a certain proportion of the sera which subsequently to the injection gave a negative reaction returned to positive at some time later.

We have related our experience with salvarsan more as a contribution to the evidence for and against this remedy than as a preliminary to the expression of any judgment on our part as to the position which it will occupy eventually in the therapy of syphilis. Any such judgment would, in our opinion, be entirely premature at this stage. Meantime our results seem to justify the following conclusions:—

1. Salvarsan has a very marked and rapid effect on the clinical manifestations of syphilis in most cases.

2. This effect is due to its action on the parasites, and is not simply a cloaking of symptoms, as is shown by the disappearance of treponemata from local lesions and the effect on the Wassermann reaction.

3. It is impossible to say at present whether this effect consists in destruction of the whole or only part of the parasites, or simply in suppression of their activity.

4. The risk in using it being so slight, no judgment against it will be justifiable till every method of administering it has been worked out.

We desire to acknowledge our great indebtedness to Major Beveridge, R.A.M.C., for the very many careful chemical analyses he has made for us, and to Lieutenant A. S. Cane, R.A.M.C., for his invaluable assistance in the notes on the cases.

# THE DIAGNOSIS OF GASTRIC CARCINOMA BY THE CLEAVAGE OF POLYPEPTIDES.

BY I. WALKER HALL, M.D. VICT.,
PROFESSOR OF PATHOLOGY, BRISTOL UNIVERSITY; PATHOLOGIST TO THE BRISTOL ROYAL INFIRMARY;
AND
G. SCOTT WILLIAMSON, L.R.C.P., L.R.C.S. EDIN.,
DEMONSTRATOR OF PATHOLOGY, UNIVERSITY OF BRISTOL; PATHOLOGIST TO THE BRISTOL GENERAL HOSPITAL.

Neubauer and Fischer (1) have proposed a laboratory test for the further assistance of the clinician in his diagnosis of cancer of the stomach. It consists of the action of gastric contents upon a polypeptide. From several quarters certain criticisms have emanated, and we ourselves are not disposed to agree entirely with the basis upon which the reaction rests, nor to regard it as specific. In spite of this, however, in connexion with an investigation upon the peptide-splitting action of pathological fluids, the test has, in our hands, yielded results suggesting an advocacy for that extended use which alone can determine its permanent utility.

### *Method.*

We perform the reaction in the following manner (modified from Neubauer):—

1. An Ewald test breakfast is given on a presumably empty stomach, and withdrawn 1 to 2 hours later. It is best to syphon off the contents and to avoid any undue manipulations with the tube. Much intra-gastric movement may lead to reflex regurgitation of duodenal fluids.

2. The stomach contents are filtered. The residue and filtrate are tested for the presence of blood, bile, trypsin, and tryptophane. If any of these are present the material is discarded.

3. One part of the filtrate is added to a solution of glycyl-tryptophane,* covered with toluol and incubated for 12–24–48 hours at 38–40° C.

4. A second portion of the filtrate is incubated for the same period with the addition of toluol, but without the dipeptide (control for tryptophane formed during incubation).

5. A tube containing glycyl-tryptophane and toluol is also incubated at 38–40° C. for 12–24 hours (control for free tryptophane in the polypeptide solution).

6. To each portion of the incubated filtrate and the control a mixture of bromine water, 3 parts, and acetic acid (5 per cent. in water) 1 part, is added drop by drop. In the presence of free tryptophane, a lilac colour develops when a sufficiency of bromine water is added (6). This colour disappears when bromine is present in excess, the mixture becoming yellow in colour. In the absence of free tryptophane the fluid assumes a pale yellow tint.

### *Fallacies.*

These are related chiefly to the presence of substances which decompose, or inhibit the decomposition of, the polypeptide.

*Vomits* cannot be used for the purpose, since regurgitated duodenal enzymes are frequently present; they may also contain free tryptophane, or yield it upon incubation. Post-mortem gastric contents are similarly useless.

*Bile.*—Although bile itself is unable to break up the dipeptide glycyl-tryptophane, its presence is indicative of the back flow of duodenal fluid containing proteolytic ferments. When either the residue or the filtrate gives a reaction for bile, the gastric contents are discarded and another test-meal given.

* This is supplied by Messrs. Kalle of Biebrich (and their London agents, Zimmermann) in small bottles ready for use.

*Blood.*—The presence of blood vitiates the test. When 1 c.c. of glycyl-tryptophane is used for the reaction, so small a quantity as 0·2 c.c. of blood effects a cleavage of the peptide (2). When equal quantities of glycyl-tryptophane and blood are employed, 0·01 c.c. of blood suffices to yield free tryptophane. If the residue or the filtrate contains traces of blood the specimen is rejected.

*Reaction.*—The total acidity and the free HCl must be estimated prior to adding the glycyl-tryptophane. The power of the gastric contents to split off the amino-group is inhibited by 0·18 per cent. HCl or 0·2 per cent. $Na_2CO_3$, after incubation for 24 hours. The reaction of the content should be brought within these limits.

*Bacteria.*—The solution of glycyl-tryptophane is kept sterile in sealed capsules, as certain bacteria are able to set free the tryptophane.

*Time.*—We have obtained a positive result in 10 hours, and as late as 48 hours. Each specimen is a law unto itself. It is advisable to withdraw portions of the incubated fluids at stated intervals, and to consider the reaction as negative only when 48 hours' incubation does not yield free tryptophane. It is scarcely necessary to add that for the longer period of incubation the reaction limit calls for special attention.

### *Results.*

These may be stated in tabular form:—

#### *Positive Results.*

*Confirmed by Operation or Necropsy.*

| Diagnosis. | Acidity. | Diagnosis. | Acidity. |
|---|---|---|---|
| Gastric carcinoma ... ... ... | 43 | Gastric carcinoma ... ... ... | 0 |
| ,, ,, ... ... ... | 45 | ,, ,, ... ... ... | 0 |
| ,, ,, ... ... ... | 26 | ,, ,, ... ... ... | 0 |

*Clinical Diagnosis.*

| | | | |
|---|---|---|---|
| Gastric carcinoma ... ... ... | 75 | Malignant liver ... ... ... | 0 |
| ,, ,, ... ... ... | 0 | Undiagnosed ... ... ... ... | 10 |

#### *Negative Results.*

*Confirmed at Operation or Necropsy.*

| Diagnosis. | Acidity. | Diagnosis. | Acidity. |
|---|---|---|---|
| Endothelioma peritoneum | 60 | Gastric ulcer ... ... ... ... | 37 |
| Gastric carcinoma ... ... ... | 30 | ,, ,, ... ... ... | 59 |
| Pyloric carcinoma ... ... ... | 113 | Pyloric stricture ... ... ... | 0 |
| Gastric ulcer ... ... ... ... | 40 | ,, carcinoma ... ... ... | 20 |

*Clinical Diagnosis.*

| | | | |

| Pernicious anæmia, necropsy | 33 | ,, ,, ,, | 0 |
| Hepatic cirrhosis ,, | 70 | Pyorrhœa alveolaris, ,, | 13 |

#### *Results to Date—Confirmed.*

| — | Positive. Carcinoma | Other conditions. + | Other conditions. − | Negative. Carcinoma. |
|---|---|---|---|---|
| Neubauer ... ... ... ... | 6 | 0 | 26 | 1 |
| Weinstein ... ... ... ... | 11 | 0 | 18 | 0 |
| Lyle and Kober ... ... ... | 6 | 0 | 7 | 0 |
| Own ... ... ... ... ... | 6 | 0 | 16 | 3 |
| Total ... ... ... ... | 29 | 0 | 67 | 4 |

#### *Criticisms.*

1. Choice of meal. Meat meals permissible.
2. The presence of polypeptide not necessary.

It has been stated (3) that it is not necessary to restrict the choice to an Ewald test meal; that a meat meal serves the same purpose; that a meat meal is preferable since the dipeptide may be dispensed with (as the meat protein derivatives yield tryptophane when acted upon by the gastric contents of carcinoma). That these statements are difficult to sustain is evident from the following table:—

*Various Meals. No Dipeptide Added.*

| Cases. | Before incubation. Ewald. | Before incubation. Meat. | 24 hours' incubation. Ewald. | 24 hours' incubation. Meat. |
|---|---|---|---|---|
| *Confirmed positive.* | | | | |
| Carcinoma ... ... ... | − | − | − | − |
| Pyloric cases ... ... ... | − | − | − | + |
| *Confirmed negative.* | | | | |
| Gastritis ... ... ... ... | − | + | − | + |
| ,, ... ... ... ... | − | − | − | − |
| Gastric ulcer ... ... ... | − | − | − | + |
| Arthritis ... ... ... ... | − | − | − | + |

Two ordinary dinners gently warmed with 2 per cent. HCl gave a positive tryptophane reaction.

The figures show that tryptophane does not appear in Ewald test meal contents either before or after incubation. It does occur before and after incubation when a meat test meal is given, and does not show any relation to cases of carcinoma. The test is, therefore, valueless when the polypeptide is not added to the gastric contents.

3. *The presence of blood is not a contra-indication to the carrying out of the reaction.*—We have shown elsewhere (2) that blood serum and exudates and transudates, &c., possess the power of decomposing the dipeptide, glycyl-tryptophane. In their original description of the reaction, Neubauer and Fischer lay special stress upon the necessity for excluding the presence of blood in both residue and filtrate. How far by the usual tests for occult or other form of hæmorrhage it is possible to exclude lymph or cell products is a question of vital interest from the theoretical standpoint. The consideration of this question may be relegated to a later communication. The essential point is, that the presence of minute traces of blood vitiates the reaction.

4. *Trypsin may be present even in the absence of bile, decompose the dipeptide, and so render the result valueless.*—This has not been our experience, as the following instances show:—

*Bile and Trypsin.*

| Material. | Number. | Bile. | Ferment. |
|---|---|---|---|
| Vomit. | 9 | + | + |
| | 6 | + | − |
| | 7 | − | − |
| Test meal. | 2 | + | + |
| | 2 | + | − |
| Post-mortem content. | 5 | + | + |
| | 3 | + | − |
| | 1 | − | + |

Coagulated blood serum plates used.

But Ohrl and Schittenhelm (5), however, when investigating the conditions associated with the regurgitation of duodenal contents into the stomach, found trypsin present in two out of a large number of cases, so that this objection must receive due weight by those who carry out or interpret the reaction. A lowered acidity of the contents or anacidity may reflexly occasion a regurgitation of trypsin. These factors should be borne in mind when devising the alterations necessary for the minimising of this fallacy. Careful removal of the gastric contents (see method) appreciably diminishes this fallacy.

Until a large number of results are accumulated we cannot say what is the real value of this reaction, but the guidance we have so far obtained has been somewhat striking. Further work may, perhaps, simplify some of the technical procedures and indicate means for the better avoidance of some of the fallacies. Kuttner and Pulvermacher (7) have already tried the substitution of "seiden-peptone" for the glycyl-tryptophane; their method presents some advantages, but is

more tedious to carry out, and the results to date are not encouraging.

While the object of this note is to suggest a wider use of this test, it would be unfair to withhold the comment that it has yet to be demonstrated that the endo-enzymes of cancer cells possess abnormal characters and activities. Still, several clinical tests whose theoretical bases have been doubted have proved of value in diagnosis.

Bristol.

# THE IODINE METHOD OF STERILISING THE SKIN.

BY PHILIP TURNER, M.S. LOND., F.R.C.S. ENG.,
ASSISTANT SURGEON, GUY'S HOSPITAL;
AND
H. C. CATTO, L.R.C.P. LOND., M.R.C.S. ENG.,
ASSISTANT BACTERIOLOGIST, GUY'S HOSPITAL.

THE iodine method of preparing the skin before operation has now been widely adopted, and undoubtedly gives excellent results. Whether the skin is really sterilised by this means can only be determined by bacteriological examination. The following investigations were undertaken with the view of determining this point. One of us (P. T.) has employed this method for over two years. At first tincture of iodine was used only as a final application immediately before the incision, the skin having been prepared and compressed in the orthodox manner on the previous day. For about the past 12 months, however, the preliminary compressing has been omitted, the solution of iodine being the only antiseptic used in the preparation of the patient's skin. In certain of the present series of cases the B.P. tincture (2½ per cent.) has been employed for this purpose, and in others the following solution: iodine, grms. 30; potass. iodid., grms. 40; aq. dest., 500 c.c. Before using this is diluted with an equal volume of methylated spirit, so that the strength of the solution is 3 per cent.

There is some difference of opinion as to whether preliminary shaving of the skin is desirable. Personally, I think it is better to do so, at any rate in adults, when the incision is to be made in the groin, the abdomen, or where much hair is present. The skin was shaved in all the cases mentioned below, and it is interesting to note that of the three cases that were not sterile one was very indifferently shaved, while in another a hair about half an inch long was attached to the minute piece of skin sent for bacteriological examination. It is here necessary to emphasise the fact, which has been insisted upon by other writers, that for the satisfactory action of the iodine it is essential that the skin shall be dry. Shaving should thus be carried out with a sharp razor without lathering the skin or, if soap and water are used, the skin must be subsequently dried with a pad or towel and then washed over with ether and again dried before the iodine solution is applied.

In acute cases the whole process is carried out on the operating table after the patient has been anæsthetised. In ordinary cases, to avoid a mess in the theatre, the preparation is carried out in the ward. The iodised area is then covered with a pad or towel. Before commencing the operation a second application of the iodine solution is made, the skin being now in a thoroughly dry condition. In the 32 cases quoted below and prepared in this manner, a thin strip of the whole thickness of the skin was removed immediately after the first incision and conveyed to the laboratory in a sterilised test-tube plugged with cotton-wool.

The investigation consisted in cultivating the piece of skin in nutrient broth for a period of 72 hours. At the end of 24 and 48 hours respectively the culture was looked at, and at the slightest suspicion of turbidity "hanging drop" preparations were made and examined. If the fluid remained clear the cultivation was allowed to proceed until 72 hours had elapsed, when it was always examined, both macroscopically and microscopically. In the cases in which micro-organisms were present nutrient agar tubes were inoculated from the broth and the particular bacterium further studied and identified. In no case did the culture show the presence of contaminating organisms from the air.

*Table showing the Results of Bacteriological Investigations.*

| No. | Nature of disease or operation. | Result. |
|---|---|---|
| 1 | Acute appendicitis. | Sterile. |
| 2 | Adenoma of thyroid. | ,, |
| 3 | Parenchymatous goitre. | ,, |
| 4 | Radical cure of inguinal hernia. | Growth of a few cocci, subsequently identified as staphylococcus albus, detected on the third day. |
| 5 | Gall-stones. | Sterile. |
| 6 | Amputation of septic finger. | ,, |
| 7 | Appendicectomy. | ,, |
| 8 | Radical cure inguinal hernia. | ,, |

All the above cases healed by primary union with the exception of those acute cases in which drainage was necessary. In none did the iodine produce any dermatitis. Though the incisions were made in very varied situations it is interesting to note that in the 3 cases in which the skin was infected the wound was in the groin. Indeed, in 9 such cases organisms were present in 3. In each case the organism present was staphylococcus albus and, as the wounds healed without any suppuration, the infection would not have been of a serious nature. How do these results compare with those obtained after preparation of the skin by antiseptic compresses?

Mr. Lockwood in the last edition of his book on "Aseptic Surgery" (1908) quotes the following three series of experiments: (1) the skin of the groin was sterile in 5 cases and septic in 6; (2) the skin of the scrotum was sterile 8 times and septic 6 times; and (3) in 45 tests, the skin being taken from incisions in various regions, 41 were sterile and 4 only were septic. Contrasting these results with the present series, it appears that the iodine method of sterilising the skin is at least as effective as the older and more troublesome method of preparation.

### A CASE OF STRANGULATED HERNIA OF THE APPENDIX VERMIFORMIS.

BY ROBERT OLLERENSHAW, M.D. VICT., F.R.C.S. ENG.,
HONORARY ASSISTANT SURGEON, SALFORD ROYAL HOSPITAL; SURGICAL REGISTRAR, MANCHESTER ROYAL INFIRMARY.

ON Dec. 18th, 1910, at 6 P.M., a male infant, aged 10 days, was admitted to the Salford Royal Hospital under my care. The mother stated that the child had not shown any signs of being ill, and had it not been for the fact that she noticed some swelling and redness of the scrotum she would not have suspected that anything was wrong. The child was breast-fed and had taken his "feeds" well. There had been no vomiting, and a good motion of the bowels had occurred on the morning of the day of admission. He was an ill-nourished baby of normal dimensions, and he lay curled up and quiet, but on being disturbed, as when the legs were straightened out, commenced to give out a series of the short exhausted cries which are so typical of infants subjected to some acute abdominal disaster. The right side of the scrotum was slightly swollen, œdematous, and of a bright red colour. The mother was not able to say how long the swelling had been present, but she had only noticed the redness whilst bathing the child in the morning. The right inguinal region was prominent and of the same bright-red tint. On palpating the scrotum the right testicle seemed to be somewhat larger than its fellow, and the scrotal integuments pitted deeply on pressure. The diagnosis was by no means obvious, and it was left between torsion of the right testis and the condition actually found.

An inguinal incision of 1½ inches was made, and a sac was exposed containing the lower inch of the appendix, which was strangulated and quite gangrenous. The internal abdominal ring was freely exposed, and the obstruction, which was at the ring, divided. The healthy remainder of the appendix was drawn down so that its base was accessible and the usual method of appendicectomy, with invagination of the stump, was performed. The cæcum was found to be very mobile, a condition frequently met with in these cases.

Some writers have stated that diagnoses of strangulated hernia of the appendix are very often incorrect, and that the real lesion present is appendicitis occurring in a hernial sac. In this case, however, the fact that the appendix above the tight constriction was perfectly healthy leaves no room for doubt as to the true condition present. The sac was separated with some difficulty from the œdematous tissues, ligatured and removed, and the inguinal canal was repaired with chromic gut sutures. No drainage was employed, and the wound healed by first intention.

The case is, of course, not an example of a rarity, but the very early age of the patient and the doubtful diagnosis make it interesting and instructive.

Manchester.

### NOTE ON A CASE OF NODULAR FIBROMYOSITIS.

BY ROBERT KNOWLES, M.R.C.S. ENG., L.R.C.P. LOND.,
CAPTAIN, INDIAN MEDICAL SERVICE.

WITH reference to Dr. W. H. Maxwell Telling's most valuable paper on "Nodular" Fibromyositis in THE LANCET of Jan. 21st, p. 154, the following notes of a case may be of interest.

The patient, aged 52, unmarried, with a history of both articular and muscular rheumatism of many years, was convalescent last May from a severe attack of bilious remittent malaria, associated with the presence of malarial crescents in the blood, and treated by rectal injections of quinine sulphate in acid solution. During the first week of convalescence, whilst one day rising from a chair, she was seized with acute pain in the lumbar region; being unable to stand, she sat down on the ground and was lifted into bed. When seen half an hour later the following conditions were found. Skin hyperæsthesia and pain on pressure into the muscles over the lower part of the lumbar region, especially marked on the right side. Movement of the hip-joints was without pain except in the lumbar muscles; and there was no pain along the distribution of the right sciatic nerve on extending it. On picking up the skin with the subcutaneous tissue in folds and rolling it over the subadjacent muscles, three extremely painful nodules, the foci of the pain, were palpable, lying over the aponeurosis. These lay exactly under the surface markings of the first and second posterior sacral foramina of the right side and second posterior sacral foramen of the left side. The upper right nodule was of the size of a large filbert; the other two were slightly smaller.

Cocaine hydrochloride, ½ grain, was dissolved in 30 minims of spiritus rectificatus, and 10 minims of the solution were injected into each nodule deeply. This procedure gave considerable relief, but only for some eight or nine hours. Subsequently a large, hot dressing of antiphlogistine was applied daily over the whole lumbar and sacral region. Thorough rubbing several times daily with iodine (1 part in 10 parts of oleic acid) was then resorted to, and the "lumbago" gradually disappeared. The patient is now (Feb. 7th) in fair health, but all three subcutaneous nodules are still palpable, and are a little tender on pressure.

Malarial neuritis, which one has read of, but not seen, was too imaginative a diagnosis. The patient was, of course, firmly convinced that the nodules were "glands," though one is not aware of any lymphatic glands in that situation. Quinine per os was taken daily during convalescence and subsequently.

Jhansi, India.

### OPERATION AT SEA ON A CASE OF STRANGULATED HERNIA.

BY STANLEY BOTT, M.R.C.S. ENG., L.R.C.P. LOND.,
LATE SURGEON TO THE ORIENT LINE.

DURING the time I was surgeon on the R.M.S. *Orsova* on her maiden voyage to Australia, shortly after leaving Marseilles I was called to one of the quartermasters early in the morning, and found a tense round tumour protruding from the inguinal canal into the scrotum. On applying taxis no result was obtained. Ice-bags were then applied and renewed for some time. Taxis was again applied with negative results. Chloroform was administered and another attempt at reduction was made, this also failing. Late in the evening the patient commenced vomiting and had a dry, brown, furred tongue, with a rapid pulse (150).

An immediate operation was decided upon and Dr. A. Corbyn, a saloon passenger, kindly administered the anæsthetic. After strict aseptic preparations, I cut down upon the hernia, successfully reduced it, and performed a radical cure. The wound healed by first intention.

The patient, it was gathered, had first suffered from hernia seven years ago, being then advised to wear a truss. This he had done till about 12 months previously to the present occasion, when, believing himself to be cured, he had discarded it. During the time of operation the ship was steaming at full speed, yet the man, making an uninterrupted recovery, was back at the wheel within four weeks.

Bude, N. Cornwall.

ASSOCIATION OF CERTIFICATED DISPENSERS.—The fifth annual meeting of the Association of Certificated Dispensers was held in the court room of the Apothecaries' Hall, Blackfriars, E.C., on March 9th, Mr. Montagu Smith, Lewisham Infirmary, presiding. There was a large attendance, the majority of those present being engaged in one or other of the public services. A satisfactory balance sheet was presented. Mr. A. Howell, honorary secretary (Dalston Dispensary), read his annual report, in which it was stated that the association continued to increase in influence and numerical strength, the number of members on the books being about 450, while the extension of the Local Government Board's orders to the Metropolitan Asylums Board service was instanced as a result of the association's activity and alertness. The meeting then re-elected for the ensuing year the three principal officers.

## ROYAL SOCIETY OF MEDICINE.

### CLINICAL SECTION.

*Exhibition of Cases.*

A MEETING of this section was held on March 10th, Sir ALFRED PEARCE GOULD being in the chair.

Mr. RICKMAN J. GODLEE showed two unusual cases of Thyroid Tumour. The first was a very chronic soft recurrent growth, the patient being a married woman, aged 54 years, who was admitted to University College Hospital in October, 1905. Four years before a small lump, of the size of a nut, had been noticed in the left lobe of the thyroid. On admission there was a mass 4 inches by 3 inches, reaching down to the sternum and pushing the trachea over to the left. It was soft and elastic and constricted in the middle by a transverse furrow. It was taken for an ordinary adenoma. It was removed through an S-shaped incision. On dividing the thin capsule very free bleeding occurred, so its outer border was quickly exposed, and some large vessels were secured. The tumour was then without delay turned inwards and shelled out without difficulty and cleanly from the gland on the inner side. But she lost a good deal of blood and was much collapsed. She, however, recovered uneventfully. Microscopically the structure of the tumour was said to be much the same as that of normal thyroid tissue, but rather more cellular. She returned in January, 1907. In the isthmus there was a hard lump rather larger than a Barcelona nut attached to the trachea, and several soft swellings occupied the right side of the neck, apparently glands, which had been first noticed in December, 1906. The glands were removed without difficulty and were found to be full of a soft growth. The apparently hard tumour in the isthmus was also really soft and broke on attempting to remove it, so the remainder was scraped away with a sharp spoon. The wound healed rapidly. The growth consisted of closely packed spheroidal cells with fine intercellular stroma, which in most places was occupied by capillaries and small blood-vessels. Scattered through the section were seen round or oval spaces lined by a single layer of cuboidal cells resembling those of thyroid tissue, most of them empty, but a very few containing colloid material. Some parts of the section showed tissue like that of lymphatic gland. Recurrence had gradually occurred in the glands on both sides of the neck, which was now occupied by large, rounded soft masses, which were moveable, but which, except from their size, caused the patient no inconvenience. A free administration of thyroid extract had not appeared to influence their growth, which was very slow. Notwithstanding the extreme chronicity of the case, it seemed doubtful if any further operation were justifiable.

Mr. GODLEE'S second case was one of Extensive Aberrant Thyroid Tumours cured by partial removal and administration of thyroid extract. The patient was a man, aged 29 years, who was admitted in June, 1908, with an extensive swelling of apparently soft glands on the right side of the neck; one larger than a large walnut was situated behind the jaw, and there was a similar lump beneath and behind the sterno-mastoid, reaching down to the clavicle. The thyroid appeared to be normal. The swellings had been coming for two or three years, and had caused slight pain. The patient had never had such swellings before. It was supposed that they were tuberculous glands, but they had more the appearance of lymphadenoma. On exposure at operation on June 6th the veins on the surface at once suggested thyroid tumours. They were all easily cleared on the outer aspect, but all were adherent on the under surface to the deep vessels by dense fibrous adhesions, which it was necessary to cut through, unless the carotid arteries, the jugular vein, and the accompanying nerves had also been removed, which was, of course, out of the question. Accordingly, when the operation was completed a hard mass as thick as the thumb was left, extending from the mastoid process to the clavicle, and no hope was entertained that further development would not occur. There was apparently no attachment to the thyroid gland, which appeared to be normal. The mass on section looked like rather brown thyroid tissue, but in the deeper parts were some masses of yellowish-white material, tougher in consistence than the rest. A microscopical section showed that the greater part consisted of tissue resembling that of the thyroid, but there were in some parts masses of small round cells. He was at once put on thyroid extract, which he continued to take for some time, and this was followed by a complete disappearance of the hard mass, and he wrote that there had been no recurrence up to the present time, that was two and three-quarter years since the operation. Mr. Godlee said that he showed these cases together, not because they were similar, but because they were both thyroid tumours and both peculiar. The first was exceptional because it was evidently a malignant growth, but the malignancy was of a very mild type. There was none of the rapid adhesion to surrounding parts, and even now, after ten years, there was very little interference with the patient's comfort or with her general health. The second was still more remarkable, because it could hardly be looked upon as a case of aberrant thyroids. The mass clinically had all the appearance of a malignant tumour. But a very incomplete removal, accompanied by the exhibition of thyroid extract, had apparently been followed by a complete cure.

Mr. C. H. PRING and Mr. ARTHUR H. EVANS showed a case of Graves's Disease and described the treatment, first by medical methods and later by excision of one of the lobes and the isthmus of the thyroid gland. The patient, a woman, aged 45 years, first sought advice in April, 1908, on account of various nervous symptoms—headache, tremblings, and excitability, with flushings. These were attributed to the menopause and treated accordingly. Improvement resulted. The patient's weight was then 8 st. 12¾ lb. In May and June, 1909, she was again suffering from vaso-motor disturbances, profuse sweatings, tremor, and rapid cardiac action, but no complaint of the thyroid gland was made and no alteration in it noticed. Belladonna and potassium bromide were given and opium later to control diarrhœa, which commenced about this time. Neither of these drugs was of much use. Phosphate of soda was given without any good effect. The patient's weight was 8 st. 6 lb. In February, 1910, the gland was first noticed to be enlarged. Thyroid extract was given and apparently did more harm than good. Rest in bed was ordered; arsenic and ergot were tried internally, with local applications of iodine in various forms. The enlargement subsided for a few weeks, but then reappeared, and suffered no further diminution in size. There was no exophthalmos, but the rapid cardiac action, trembling, sweating, and diarrhœa were increased, and gave rise to considerable anxiety. Loss of weight continued (7 st. ½ lb. in July, 1910). Suprarenal extract was given, and the changes were rung on all the drugs recommended, but in no single instance was any good effect seen. In August, 1910, the patient was very ill and went to Broadstairs for a month. After her return she was exceedingly emaciated, the pulse was very rapid and irregular, there was commencing exophthalmos, the diarrhœa was persistent, and her condition altogether caused the gravest fears. Her weight had fallen to 6 st. 7 lb. It was obvious that unless some radical change could be made in her condition the patient would not live many weeks, and although the gland was by no means large the question of operation arose. Mr. Evans saw the patient on Oct. 7th, 1910. The pulse was then 130 and irregular; the heart's impulse was "bounding"—there was no cardiac murmur; she had marked tremors; her weight, which originally was 9 st. 2 lb., when taken two weeks ago was 6 st. 7 lb. There was no obvious exophthalmos, but slightly marked von Graefe's sign. She felt as if she "could not get her breath," and if she happened to be in a hot room she had to "come out gasping." The vocal cords moved freely, and the trachea showed no indentation. On Oct. 13th there was marked augmentation of the symptoms. She had obviously wasted, and she weighed not more than 6 st.; the right lobe of the thyroid had increased in size, and the left was beginning to enlarge; the pulse was very irregular and uncountable at the wrist, but listening over the heart it was reckoned at 148 and 152 per minute; there was marked pulsation in the neck. The following day the right lobe and isthmus of the thyroid were excised. The anæsthetic was given by Dr. Cecil H. M. Hughes and the patient occasioned him no anxiety. There was nothing worthy of note as regards the operation save that there was a good deal of trouble in

"shelling out" the thyroid, the loose (veal-like) connective tissue, out of which the thyroid is usually shot with a sweep of the finger, being more fibrous and more firmly adherent to the surface of the gland than usual, so that some vessels were torn in the separation. The gland was so adherent to the upper rings of the trachea that the gland in that situation was torn through leaving a thin layer of the thyroid adherent to the trachea. Into the lowest part of the wound a gauze drain was inserted and also a rubber drainage-tube, the lower end of which was brought out through a small opening above the sternal notch. Two hours afterwards the pulse was 120 and regular. Next day the dressings were changed and were sopping with secretion from the torn surfaces of the thyroid. On the second day after the operation the pulse-rate was 120 and 104; on the third day 98 and 106; on the fourth 100 and 88; and from that day onwards it was about 88. On Nov. 3rd, when the patient left, the weight was 7 st. She wrote on Dec. 9th saying: "I am now 8 st.; I have a very good appetite without the aid of medicine; I feel quite a different being, and life is now worth living." On Jan. 8th she wrote: "I am now 8 st. 8 lb. I think I am quite fat enough."

Mr. W. TROTTER described a case of Carcinoma of the Thyroid in which the patient had been operated on by him 3½ years ago, the condition then showing extensive involvement of lymphatic glands. There was no recurrence.—A discussion followed in which Dr. LEONARD WILLIAMS, Dr. R. HUTCHISON, Dr. W. P. HERRINGHAM, Mr. C. GORDON WATSON, and Mr. W. SAMPSON HANDLEY took part.

Mr. H. A. LEDIARD (Carlisle) described a case of Benign Cyst of the Tibia. The patient was a girl, aged 14 years, who was brought to the Cumberland Infirmary on August 14th, 1910, on account of a large swelling in the lower third of the left leg, which had been growing for nine months, so far as it had been observed. At first there was no pain, but more recently, when weight was put on the leg, as in walking, pain was felt. During the three months prior to admission the swelling in the leg had increased considerably. On the left leg a well-marked swelling of the tibia was seen, which involved the lower third of the bone, reaching almost to the ankle-joint. The swelling was uniform in outline and pear-shaped, the widest part being above the ankle, and the apex tapered off into the normal bone above. The swelling was firm to the touch, and the skin over it was tightly stretched, but not adherent. No egg-shell crackling was obtained. There was no alteration in the colour of the skin over the swelling, nor were any vessels visible. No tenderness was present except on firm pressure. There was no rise of temperature locally or generally, and the general condition of the girl called for no comment. In order to discover the nature of the swelling a trephine was used over the inner aspect of the swelling. The bit of bone removed was exceedingly thin, and presented no obstacle to the saw. The finger discovered a large cavity in the bone, which contained a clear watery fluid, slightly tinged with blood. No spicules of bone were detected, but a smooth thin membrane lined the cavity. The bone appeared to be very thin and expanded uniformly all round. The fluid from the cyst was not saved for examination. A few days later the limb was amputated at the knee-joint. The girl recovered and left the hospital on Oct. 1st. The swelling of the bone was consistent with a sarcoma, or with tuberculous disease of the medulla, and, as matters turned out, with a cyst of the bone. The absence of constitutional disturbance gave no indication in any special direction. There was no egg-shell crackling. The age of the girl favoured the presence of sarcoma, but the surface of the swelling was even all over and shaded off above into the normal bone at the junction of the middle and lower thirds of the limb. When the trephine was used it was seen that an expansion of the bone into a thin shell was the disease to be dealt with. Prior to any interference a radiograph was taken, and it showed a uniform smooth-surfaced swelling of the tibia, and a light shadow in contrast with the dark one of the healthy bone of the shaft above the cyst. At the lower part the swelling ended abruptly at the level of the epiphysis. To those experienced in the radiography of bone cysts, the radiograph of this case might be conclusive. Beck was the first to allude to the diagnostic differentiation of bone cysts by radiography. He said, "The radiograph yields a clearly bounded line of cortex of the thickness of letter paper, forming a frame for a quite transparent oval surface of spindle form. The cohesion of the outer rind is nowhere broken. The epiphyses are normal."[1] Lexer had attributed a high value to the radiography of bone cysts, but other observers had not been so impressed. Rumpel had concluded that cysts of bone could be distinguished from sarcomata by radiography. In 1907 Jones and Morgan wrote on "Benign Cysts of the Long Bones," and stress was laid by them on the value of radiography in the diagnosis. Since then Mr. Hugh Lett had published a radiograph of a cyst of the humerus upon which he operated with success.[2] There could be no doubt that radiography was of great value in aiding the diagnosis of these cases, even if it could not be said to give a conclusive verdict when it was brought into use in bone cysts. In Mr. Lediard's case the radiograph showed no thin dark line bounding the cyst suggestive of the thin shell of bone which was found and could be seen in the specimen or photograph. Amputation was resorted to because the diagnosis leaned to a malignant growth, and not because the limb might have been unserviceable if a less drastic means had been adopted. The cyst measured 3¼ inches in length and 2½ inches in breadth. The shell of the bone was very thin, and before long egg-shell crackling would have been present, and a great liability to fracture. The growth of the cyst was actively proceeding in all directions, upwards in the shaft of the bone, backwards in the direction of the Achilles tendon, forwards as well as downwards, invading the epiphysis. Microscopically there was no evidence that the cyst had developed from a growth, and no cartilage was found in connexion with the cyst formation. The formation appeared to be caused by a process of absorption, probably starting in the marrow and gradually extending outwards with expansion of that part of the shaft.

Dr. HUTCHISON showed a case of Splenomegaly (? Congenital Family Cholæmia), and two cases of Secondary Anæmia associated with Achylia. Referring to the last two cases, Dr. Hutchison pointed out that achylia was well known in association with pernicious anæmia, and that the cases suggested that any severe anæmia of long duration might also be associated with it. He drew attention to the persistence of the achylia in the first of the two cases after the disappearance of the anæmia, and commented on the simulation of latent carcinoma of the stomach by such cases.

Dr. JAMES COLLIER and Mr. J. P. LOCKHART MUMMERY showed a case of Tabes Dorsalis with early rectal crises.

Dr. LEONARD G. GUTHRIE exhibited two cases of Muscular Atrophy of the Peroneal Type (Charcot, Marie, Tooth) in father and son.

Dr. HERRINGHAM showed a case of Septic Gastritis.

Mr. EVANS furnished a subsequent report on a case of Excision of the Larynx, Lower Part of the Pharynx, and Upper End of the Œsophagus for Malignant Disease (Squamous-celled Carcinoma) of those structures. The patient, a female, aged 40 years, was shown at a meeting of the Clinical Section on Nov. 12th, 1909.

## SECTION OF ANÆSTHETICS.

### *The Use of Scopolamine and Morphine, Atropine, and Similar Drugs by Injection before Inhalation Anæsthesia.*

A MEETING of this section was held on March 2nd, Dr. W. J. MCCARDIE, the President, being in the chair.

Dr. DUDLEY BUXTON, who opened the discussion, pointed out that the use of combined anæsthesia—that is, the employment of some narcotic or alkaloidal drug given antecedently to the inhalation of a general anæsthetic—was no recent innovation. Claud Bernard, Regnier, Julliard, Dastre and Morat, Demarquey, and many others had advocated and practised the method. The use of morphine before chloroform or ether had been shown to possess certain drawbacks, so that it was not until Schmidt isolated scopolamine, and it was shown by Schneiderlin that this drug, combined with morphine, rendered it possible to avoid many of the dangers of morphine when given alone, that the recent revival of the combined method became possible. The school represented by Gauss, Korff, and others had attempted to use these drugs alone and to produce the "dämmerschlaf," or dawning sleep, in lieu of inhalation anæsthesia. Outside the confines of midwifery this method, whatever its merits within that restricted area, had proved insufficient for general surgery. To supplement it the practice had grown of employing these drugs alone or

[1] Archives of Clinical Surgery, vol. lxx.
[2] THE LANCET, Oct. 22nd, 1910, p. 1202.

associated with other alkaloids by hypodermic injection and following this by inhalation of ether, chloroform, and other general anæsthetics such as nitrous oxide, as advocated by Dr. Crile, chloride of ethyl, and various mixtures and successions. Those who had pursued this plan had published series of cases, some spoke in favour, others were less certain of the merits of the procedure. Again, scopolamine had been recently advocated to obviate the nervous strain which all feel was the worst feature incident to intra-dorsal injection. The speaker pointed out that as yet the subject was only in the stage of trial. We had yet to learn its dangers and the best technique, and to decide what drugs and what doses should be given. It was time that the pharmacology of scopolamine and morphine was well known, but we had yet to obtain experience of their interaction with general anæsthetics, especially under the varying conditions presented by patients suffering from multifarious pathological lesions. He quoted a number of authorities and gave their results, which upon the whole were favourable. That the method of combined anæsthesia presented special difficulties and dangers he admitted, but he submitted that the former were capable of being minimised by care and forethought, and the latter would disappear when the technique was better understood and more carefully elaborated. In reference to the actual drugs, the speaker spoke of the researches of Dr. Sahli, who proposed using the chlorides of the alkaloidal bodies of opium as safer than morphine, and guarding the effects of scopolamine by attention to the requisite dosage of individuals. Atropine became, he thought, an essential addition when open ether was used, as although scopolamine produced similar effects, yet when combined with morphine its action in that direction was insufficient to counteract the injurious results of unstinted doses of ether. In the mutually synergent action of alkaloids associated with general anæsthetics, especially when oxygen was used, Dr. Dudley Buxton believed that the best results were obtainable. The method removed pre-anæsthetic alarm, lessened the amount of the general anæsthetic, and so diminished after-effects, and gave prolonged post-operative sleep and mental tranquillity.

Dr. H. MACNAUGHTON-JONES said that he had been using scopolamine-morphia and chloroform anæsthesia in serious abdominal and pelvic operations for nearly five years. The great majority of these had been done under this method. A subcutaneous injection of 1/6 gr. of morphia and 1/100 gr. of scopolamine were given the night before, after the bowel had been well emptied; a second injection was given the following morning, after a rectal enema; and one hour before operation 1/36 gr. of strychnine and 1/100 gr. of atropine were administered subcutaneously. In some instances only one injection was given, that on the morning of the operation. He had only had time to look up the last 30 of his cases, which might be taken as typical of the effect and advantages of this form of anæsthesia. In regard to vomiting, in 18 of these cases there had been little or no sickness; some sickness occurred in the instance of five patients on the day of operation; and four had not vomited until the second day. Only in one case had there been persistent vomiting. In this three cœliotomies had been performed at comparatively short intervals. It was clearly a case of idiosyncrasy. The patient had been operated upon previously under chloroform anæsthesia, and there had been persistent vomiting for some days. The condition antecedent to operation was, as Dr. Dudley Buxton had stated, favourable, from the calm and rest of the previous night, and her indifference at the time of operation. There was the great advantage of the minimum of chloroform in proportion to the severity and length of operation, as well as the certainty of the quantity inhaled. There was decidedly a better condition the day of the operation, greater calm and less pain. In not one single instance in any of the operations had an untoward symptom arisen from this method of administration. He spoke in praise of the Vernon-Harcourt regulator, of which he had had experience since it had first come into use. He had not used scopolamine and morphia with ether. He had reserved its administration for abdominal operations. He thought that the time had arrived when, with their present knowledge, anæsthetists might more definitely formulate the conditions demanding certain methods of administration and the nature of the anæsthetic indicated. Thus greater uniformity of administration would be arrived at.

Mr. F. S. ROOD recorded 300 cases and furnished the following particulars. The injection of scopolamine, morphia, and atropine, 1/100, 1/6, and 1/120 grain respectively, was given 45 minutes before operation. The patient was then left in bed with screens around or in a darkened room. The anæsthesia was commenced in bed and complete surgical anæsthesia obtained before moving the patient. In the first 50 cases 1/100, 1/120, and 1/6 grain of scopolamine, atropine, and morphia respectively were given to the women, while in the case of the men a preliminary injection of 1/6 grain of morphia one and a half hours before operation was also given. In the remaining 250 cases all received 1/100, 1/120, and 1/6 grain, with the exception of ten children between 10–16 years, who each received 1/120 of scopolamine, 1/120 of atropine, and 1/8 of morphia. In 167 cases the patient was profoundly asleep at the time of induction of anæsthesia, in 131 cases very drowsy and indifferent, and in 2 cases no narcotic effect was produced. In 40 cases ether by the open method was employed from the commencement. It was found that the pungent ether vapour sometimes caused those patients who were only drowsy to wake up. In 260 cases anæsthesia was induced with chloroform by the open method and continued with ether. In most cases the respirations during operation were indistinguishable from, or even quieter than in, chloroform anæsthesia. In 15 cases of men of a plethoric, muscular type the respirations were certainly exaggerated, but even in these cases the movement of the abdomen was certainly much less than with ether alone. There was a marked insusceptibility to reflex troubles, respiratory or cardiac. Of 20 cases of thyroidectomy, including 12 exophthalmic goitres, there was stridor during the enucleation in one case only, and in no case was the pulse accelerated. The relaxation obtained appeared to be in direct proportion to the amount of ether given. The absence of mucus was a great advantage whilst maintaining a deep anæsthesia, whilst the quiet respirations were obviously an advantage in abdominal surgery. As to after effects, the patients usually remained unconscious, breathing regularly from 3–5 hours after operation. In 23 cases in which the operation lasted over two hours the average period of unconsciousness was six hours; in 5 cases where there was rather severe shock, lasting seven hours. With regard to after vomiting, 144 cases did not vomit at all; 135 cases vomited once or twice; and 21 vomited several times during the first few hours after recovering consciousness. In those cases where vomiting occurred it did not take the delayed type. He concluded that from the point of view of the patient the method blotted out or robbed of its terrors the preliminaries of an operation, which in some cases—as, for instance, exophthalmic goitre—was a very real advantage. Also it diminished the discomforts of after-pain, &c., by lengthening the period of unconsciousness, and vomiting certainly seemed to be lessened. From the point of view of the operator the quiet respiration and relaxation which were usually obtained were of great assistance, and finally there was the undoubted advantage of being able to substitute, with equal results, a safe drug like ether for a dangerous one like chloroform.

Dr. J. BLUMFELD stated that he had used morphia and atropine before various general anæsthetics, and considered that less mucus and additional quiet were obtained. He had heard from Mr. H. M. Page, a member who was unable to be present, of cases of respiratory difficulty and actual cessation of respiration from morphia administered too shortly before the operation, its effects deepening while this was proceeding.

Dr. G. A. H. BARTON said he used 1/100 grain scopolamine and 1/6 grain morphia three-quarters of an hour before operation. He found it specially useful in laryngeal and œsophageal work. He found induction shortened and abdominal rigidity diminished. The open ether method was used. There was also less tendency to shock, which counterbalanced the occasional tendency to respiratory difficulty.

Dr. J. F. W. SILK said the subject under discussion was not new, but had come up at intervals during the past 20 years. There was difference of opinion as to rigidity, some finding less, others more, when scopolamine and morphia were used. In the latter cases he thought probably too little anæsthetic was used. There was also a good deal of uncertainty about the duration of stupor and the frequency of vomiting.

Mrs. DICKINSON BERRY stated that she had used atropine and morphia, 1/100 and 1/6 grain, in some cases and thought that vomiting and restlessness had been increased. Scopolamine had recently been added in a few cases and better results were obtained.

The PRESIDENT considered that the effects of the drugs

depended largely on what preparations were used. He found some of the German preparations were far more satisfactory than any of the English ones. He used them when light anæsthesia was required, and found the effect was to deepen the anæsthesia from the surgeon's point of view and to lighten it from that of the anæsthetist. With regard to atropine, he observed that though it was considered generally to stimulate the heart, recent investigations made by Webster of Winnipeg pointed to its producing a paralytic effect on heart muscle.

## LARYNGOLOGICAL SECTION.

*Exhibition of Cases and Specimens.*

A MEETING of this section was held on March 3rd, Dr. P. WATSON WILLIAMS, the President, being in the chair.

Professor HOBDAY, F.R.C.V.S., gave a short address, and showed specimens of the Equine Larynx illustrating the results of the "ventricle stripping" operation for the relief of the conditions known as "whistling" and "roaring" in horses. The operation consists in removing the mucous membrane completely from the pouch or ventricle at the back of the paralysed vocal cord with the idea that two raw surfaces will thus be made, the two sides of the ventricle adhere together, and thus completely obliterate it. It thus follows that the paralysed vocal cord which is the cause of the "roaring" must of necessity be retracted out of the lumen of the larynx, and become firmly adherent to the wall of this organ. An interesting discussion followed, and it was generally considered that the operation could have but a very limited application as regards the human larynx.

The PRESIDENT showed a case of Carcinoma of the Larynx operated on for malignant disease on Nov. 9th. The patient was a woman aged 40 years. The voice was good, but some members were of opinion that signs of recurrence were present.

Mr. J. GAY FRENCH: Endothelioma of the Palate with Metastatic Growths in the Neck, which had derived great benefit from treatment with radium, the amount used being 50 milligrammes.

Mr. HERBERT TILLEY: 1. A Portion of a Rabbit's Bone removed from the Right Bronchus after three years' impaction, and which had produced signs of bronchiectasis. Skiagraphy in this case had failed to reveal the presence of any foreign body. 2. A Tooth removed from the floor of the right maxillary antrum.

Dr. W. H. KELSON: Tumour of the Right Side of the Neck involving the Pharynx, in a woman aged 30 years. The growth was a very slowly growing sarcoma, taking origin apparently from the transverse processes of the cervical vertebræ. Owing to the agonising pain suffered an operation had been performed by the exhibitor and as much as possible of the growth removed, with complete relief to the pain. Rapid healing had taken place.

Dr. L. HEMINGTON PEGLER: (1) A case of Ulceration of the Pharynx in an old man, possibly connected with pyorrhœa alveolaris; (2) Party-wall Cancer of the Larynx and Œsophagus in a woman aged 45 years; and (3) Tuberculosis of the Larynx in a woman aged 55 years.

Dr. DAN MACKENZIE: 1. Antrum Suppuration treated by Nasal Antrostomy, followed by blocking of the nasal duct. The exhibitor thought that the duct must have been wounded at its lower end at the time of the operation. (In the discussion that followed the view of many members was that temporary epiphora after the radical operation on the maxillary antrum is not uncommon.) 2. Cicatricial Obliteration of the Naso-pharynx due to Hereditary Syphilis. The patient was a male, aged 27 years. When first seen the soft palate was found to be caught up and adherent to the posterior wall of the naso-pharynx, and was practically represented by a mass of scar tissue. Through this a small foramen led into the nose. Attempts were made to dilate the opening with a laminaria tent, which broke off, leaving a piece inside. Ulceration followed with formation of a clear opening, the result being that the patient could now blow his nose satisfactorily.

Dr. H. LAMBERT LACK: A woman with (?) Lupus Erythematosus of the Mucous Membrane of the Cheeks of over 12 months' standing. Various treatments had been adopted, including removal of all the teeth, under the impression that the cause might be sepsis, but nothing had so far been found to cure it.

Mr. SOMERVILLE HASTINGS and Dr. KELSON: Burrs of Special Shape and Construction for use in the radical maxillary antrum operation, by the intranasal route.

Dr. W. JOBSON HORNE: Loss of Voice in a young man, aged 20 years. It had come on gradually over two years, getting much worse during the last four or five months, and was accompanied by dysphagia. Sputum was plentiful and physical signs were present in the chest.

Mr. FRANCIS F. MUECKE: A case of "Ventricular Voice" in a woman aged 28 years; hoarseness was first noticed when three years old, after scarlet fever. Since about 15 years old the voice had got gradually better. The general health of the patient was good. The left vocal cord could not be seen; the right was atrophied; the ventricular bands were rounded, large, and on phonation came closely together, the arytenoids turning inwards and assisting to close the glottis.

# SOCIETY OF MEDICAL OFFICERS OF HEALTH.

*The Treatment of Phthisis by Industrial Insurance.*

A MEETING of this society was held on March 10th, Dr. W. G. WILLOUGHBY, the President, being in the chair.

Dr. T. D. LISTER read a paper upon the Treatment of Phthisis by Industrial Insurance, with special reference to the Benenden Sanatorium. He said that among the industrial classes the want of immunity to consumption chiefly depended upon ignorance, lack of sunlight, fresh air, and ventilation, and lack of a certain standard of living. Immunity to the disease was usually lost slowly and with difficulty, and with much greater difficulty than it was ever regained. While the conditions under which many of the working classes spent their time remained as they were, progress towards a successful conclusion of the anti-tuberculous campaign was bound to be slow. The greatest difficulty to be faced was an educational one. After giving an account of the steps in the development of the German system of insurance of workmen, he referred to the formation of the National Association for the Establishment and Maintenance of Sanatoria for Workers, which erected in 1906 the Benenden Sanatorium in Kent. Beds in this institution may be maintained by workers' organisations at an annual charge of £65 per bed and by local authorities of £78 per bed. Additional temporary accommodation may be obtained by workers' organisations at a cost of 25*s.* per week for each bed, and by local authorities at a weekly cost of 30*s.* per bed. Poor-law patients are not received into the sanatorium. The average weekly cost of each patient is 26*s.* 1*d.* Taking into account the condition on discharge, 81 per cent. of those who left the sanatorium with the disease "arrested" were still doing full work from more than six months to more than two years after their discharge, while 37 per cent. of those who left as "improved" and 7 per cent. of those who left "unimproved" were doing full work at the same periods after discharge. Among workers' organisations the largest amount of support of the institution comes from the Post Office employees, nearly 50,000 of whom subscribe 2*s.* annually to the funds. After referring to the inactivity of the great friendly societies as regards the cure of consumptive patients, although they were paying away over £1,000,000 yearly in the relief of those suffering from the disease, Dr. Lister expressed the opinion that this inactivity was due to the fact that the disease arose in faulty educational methods, in faulty hygienic conditions of employment, and in bad housing, and because the admission of the name of the disease often meant, under present conditions, the break-up of the home.

Dr. J. R. KAYE and Mr. HERBERT JONES spoke in approving terms of the arrangements which they had seen at the Benenden Sanatorium.

Dr. F. C. SHRUBSALL urged that the success of a sanatorium was mainly due to its management, and that a suitable superintendent was more important than a suitable locality or elaborate arrangements for ventilation and the prevention of dust traps. Sanatorium patients must be taught the best way to manage their lives when they returned to their homes, so the institution arrangements should approximate to those in the homes. He emphasised the importance of a patient returning to his own work, and not to work apparently less

arduous but most probably also less well paid. Starvation was a worse disease than tuberculosis.

Mr. C. H. GARLAND advocated the extension of the Edinburgh method of dealing with tuberculosis to the whole kingdom. This, he considered, was too vast an undertaking for voluntary effort, and could only be carried out by the State under some system of insurance.

Dr. J. S. TEW urged the importance of simplicity in sanatorium treatment and of making the patients perform suitable work.

Mr. E. H. T. NASH pointed out that it must be brought home to the working classes that the prevention of tuberculosis was a working class question. He considered that a main factor in dealing with the disease was food, and agreed that every patient should be encouraged in the hope of returning to his own work.

Dr. C. SANDERS spoke of the importance of dealing with the family of a consumptive bread-winner.

Dr. W. BUTLER and Mr. F. E. FREMANTLE also took part in the discussion.

## EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

*Duodenal Ulcer: its Diagnosis and Treatment.*

A MEETING of this society was held on March 1st, Dr. BYROM BRAMWELL, the President, being in the chair.

Professor F. M. CAIRD introduced a discussion on Duodenal Ulcer; its Diagnosis and Treatment. He said that of recent years their knowledge of gastric and allied affections had been advanced by the freedom with which abdominal exploration was practised in order to substantiate a diagnosis, to combat certain symptoms, and to establish a definite line of treatment. As a result of this their appreciation of the relative value of symptoms had been increased, and they were in a better position than formerly to judge the rôle these should play in guiding them to a definite conclusion; they could with greater accuracy recognise special ailments and the treatment appropriate to each. It would be conceded that a correct diagnosis was their highest aim, and could they only formulate a definite method of obtaining this with sufficient exactness the question of treatment would be practically settled. As to the diagnosis of duodenal ulcer, it had been asserted that certain prominent symptoms might be grouped together as peculiar to duodenal ulcer which were not common to gastric ulcer. This important symptomatic differentiation originated mainly in the Leeds School, and they might here acknowledge their debt of gratitude, more especially to Mr. Moynihan, for the stimulating, dogmatic, and bold pronouncement he had made on this subject. Moynihan held that a careful elucidation of certain symptoms apart from any objective examination of the patient might lead them to form a correct diagnosis as to the existence of duodenal ulcer. He believed that in typical instances there would be found a long-standing history of intermittent dyspeptic attacks, aggravated during the colder seasons, occurring chiefly in males from 25 to 45 years of age, characterised by gastric discomfort and pain, which followed two to six hours after the chief meal, gave rise to a sense of hunger, was relieved by taking food, and frequently awoke the patient during the night. Hæmorrhage, a late symptom, took the form of melæna; and vomiting, infrequent, became more pronounced as stenosis due to cicatrisation progressed. Beyond local tenderness present in some cases they were informed that there was no objective sign of substantial value, and it was indicated that a test meal usually showed less free HCl than normally. They were therefore presented with features which differed considerably from those commonly met with in chronic gastric ulcer, in which condition they found that pain came on shortly after ingestion of food and was not relieved by eating, where the hæmorrhage took the form of hæmatemesis, where vomiting might be frequent, and where the HCl was increased. While they admired the happy terms and trenchant style in which Mr. Moynihan expressed the duodenal ulcer syndrome, they were not clear that it was so easy to differentiate from symptoms alone the position of ulcers which might lie in such close neighbourhood as on one or other side of the pylorus. They were ready to welcome and admit the general truths he stated, but Professor Caird had met with cases where no duodenal ulcer existed although the typical symptoms were present, just as in their entire absence the ulcer might occasionally be disclosed. Professor Caird narrated an illustrative case. He was also able to recall cases of perforated duodenal ulcer which had exhibited no antecedent symptoms. They might leave to the physician the important task of indicating the more salient points in diagnosis which enabled one to differentiate between the allied forms of ulceration, the results of hyperchlorhydria, the various types of dyspepsia due to latent or hidden appendicitis and cholelithiasis, since they were chiefly concerned with the early, and therefore less pronounced, manifestations of these affections in which their diagnostic acumen was of such service. He believed that the application of general principles, careful consideration and examination should preclude error even in difficult cases. He had noted that the test meal in cases of duodenal ulcer showed the presence of HCl in excess. He also looked to the physician for a statement as to what seemed the most useful lines of treatment, for it would be naturally believed that, if the patient sought advice during the early stages of duodenal ulcer at least, healing might be effected under suitable care and regimen. The fact that recurrence might take place at a later date after apparent cure, just as it might follow, although more rarely, surgical intervention, left them with a suspicion that they had not yet arrived at the primal source of the disease. That duodenal ulcer was most prone to originate in the first part of the duodenum, and became less frequent as they receded from the area which received the acid outflow from the stomach, had long been recognised. Fuller information was required as to the sex incidence, and they wished to know the cause of the initial death of tissue which left an ulcer which refused to heal as long as it was washed by the acid gastric contents. Was the ulcer of embolic, toxic, or traumatic origin? Failure to detect a duodenal ulcer even after surgical investigation had been followed by the actual demonstration of such after death. As to the appearance of the ulcer, Professor Caird had observed (1) silvery white patches of about the size of a threepenny piece, sometimes rather stellate in outline, superficial in character, and with the slightest or almost no trace of thickening; (2) cicatricial puckerings with adhesions and pouches and varying degrees of stenosis but with well-developed crateriform thickenings had been rarely met with; and (3) large tumour-like inflammatory masses adherent to the liver and gall bladder, and free from the pylorus. Such conditions might by traction evolve symptoms which complicated the diagnosis. Surgical treatment of duodenal ulcer consisted primarily in the formation of an anastomosis between the stomach and the jejunum. The curative effect was ascribed to the local rest which was given to the affected area. It was practically a system of drainage whereby the irritating gastric contents were diverted from the normal route through the pylorus and duodenum; in addition to this, the alkaline contents of the duodenum mingled with the gastric secretions and mitigated their acidity. They were aware that the natural functions can even be well performed after loss of the pylorus, and the screen had shown that the aperture in gastro-enterostomy might assume the function of the pylorus until such time as the ulcer healed. He had no desire to emphasise the surgical aspect of treatment, but as a rule posterior gastro-jejunostomy was recognised as the principal curative agent, but with it some surgeons believed that it might be combined with adjuvant treatment of the local lesion in the shape of excision of the ulcer, infolding or inversion of the affected area, or complete closure of the pyloric ring. Others again had not hesitated to excise the whole segment of the affected bowel, following this up by an end-to-end junction. That such measures should become a matter of routine he doubted; excision in any form meant increased risk. It might be admitted that total closure of the gastric outlet might ensure greater rest to the affected area, but it was questionable if the gain was so marked as it might appear at first sight, since in the presence of a gastro-jejunostomy all the food was apparently transmitted by the new route only, and the pylorus did not resume its function in this way until the ulcers had healed. It might be urged that closure of the pylorus effectively prevented a *circulus vitiosus*, but this did not occur in well-executed operations. It might also be advanced that greater security was afforded to the patient, and that by such additional measures less opportunity was

afforded for the return of ulceration. But it had to be remembered that recurrence might take place after surgical operation for duodenal ulcer, although personally Professor Caird had no such experience, and it had yet to be established that the various tempting additions to a simple gastro-jejunostomy lessened this tendency to any marked degree. The results of operation were brilliant, and he could not recall a single instance where a gastro-jejunostomy practised for a duodenal ulcer had been followed by a return. Examination of the gastric contents months after operation had given varied results. It might be noted that in some instances the excessive acidity had been restored to the normal standard. The question of interference to check hæmorrhage in the form of a melæna which threatened life was one in which he had had no experience. In one case a simple gastro-jejunostomy performed for duodenal ulcer with fibrous induration and adhesions, all left undisturbed, was succeeded immediately by severe pain and symptoms which simulated those of perforation. The pallor, small pulse, and lack of abdominal rigidity gave the key to the situation, and the evacuation of large quantities of blood proved what had occurred. Perforation of a duodenal ulcer exhibited symptoms which as a rule differed only in degree from those of similar gastric lesions near the pylorus. The history or lack of history of indigestion, right-sided tendency of the pain and tenderness might aid one in arriving at a diagnosis. A diagnosis between gastric and appendicular perforation was often not easy.

Dr. WILLIAM RUSSELL said that on the subject of duodenal ulcer there had been a great deal of confused writing. He ventured to submit certain propositions which were the result of his own experience: First, duodenal ulcers were in all respects analogous to gastric ulcers and might be classified as acute, chronic, and perforating; secondly, in both duodenal and gastric ulcers marked disturbance of the gastric functions preceded or was associated with the lesions. There were exceptions to this rule, however. The chief gastric disturbance was hyperchlorhydria. One point had to be borne in mind, and that was that the lesion in both acute gastric and acute duodenal ulcer might, judging by its speedy recovery, be a superficial erosion, although associated with hæmorrhage. In the diagnosis of duodenal ulcer one must be able to differentiate between, and to treat successfully, the different disorders of gastric function, because on the *failure* to remove certain symptoms the diagnosis of duodenal ulcer might depend. Acute duodenal ulcer often came on during the course of an attack of hyperchlorhydria. Acute ulcer was in his experience easy to cure as a rule. Within the last few months Dr. Russell had seen three cases of acute duodenal ulcer associated with severe melæna, and all had rapidly recovered on appropriate diet and medical treatment. Duodenal ulcer might heal as completely and speedily as gastric ulcer. The very fact that one failed to arrest melæna or the pain which ensued two hours or more after taking food was almost a certain proof that the case was one of duodenal ulcer. Then as to chronic duodenal ulcer, some physicians thought that they could cure such cases without gastro-enterostomy. He had doubts as to these being cases of chronic ulcer, and thought that possibly they were cases of derangements of stomach function. When he was convinced that he was dealing with a chronic duodenal ulcer he did not spend much time in endeavouring to effect a cure, but soon advised gastro-enterostomy. Lastly, as to perforated duodenal ulcer, it, of course, required operation. In a case of this kind to which he referred, the earliest symptoms of duodenal ulcer had been ignored in spite of melæna, the ulcer having developed after years of recurring hyperchlorhydria. Other points he had not time to refer to.

Dr. T. W. DEWAR (Dunblane) asked if Professor Caird had noted a history of heredity in such cases. He knew of a grandmother who died either from gastric or duodenal ulcer. She had a family of six; three of these suffered all their lives from dyspeptic symptoms, and one had four children of whom two had had gastrostomy performed. Dr. Dewar himself had suffered from duodenal ulcer with acute discomfort, attended with intervals of good health, though he did not think that the ulcer had ever really been healed. He was seized suddenly with vomiting, which persisted until he was operated upon. The cure had not been entire, and he had had two attacks of melæna.

Dr. GEORGE A. GIBSON said that on looking over his case-books he found that the general expression of hyperacidity was not borne out by his own observations in cases of true duodenal ulcer. The total acidity varied from 0·1 to 0·26 per cent., or a condition of hypo-acidity to slight hyper-acidity and the free acidity varied from 0·02 to 0·18 per cent.; the condition of acidity varied very widely. In cases of recent hæmatemesis or melæna he never dreamt of getting a test meal as its very withdrawal might do harm. He believed that the gastric spasm which accompanied duodenal ulcer prevented the passage of the acid gastric contents after operation. He found it very difficult to separate between acute and chronic duodenal ulcer, and even the diagnosis of this form of ulceration was difficult. He had diagnosed this affection, and at the operation either nothing abnormal was found or it might be a case of gall-stones or appendicitis. He doubted much as to the possibility of accurate diagnosis. He took a gloomy view as to treatment and was sceptical as to the healing of chronic ulcer, and indeed he was of opinion that it did not heal, though the acute ulcer might. He unhesitatingly called in the surgeon's aid at the earliest possible moment whenever he was sure of the disease, and he thought it best to close the pylorus completely as then the best results were obtained.

Mr. C. W. CATHCART said that the mortality in perforated duodenal ulcer was very high. Of 8 cases, 6 were fatal and 2 recovered. In 5 of these there was the typical hunger-pain from 1½ to 2 hours after taking food; in 3 symptoms of chronic dyspepsia were present, and in 1 only slight epigastric pain. Of 25 cases of perforated gastric ulcer, 12 died and 13 recovered, and in the majority of these dyspepsia and pain shortly after taking food were complained of, though in some typical hunger-pain two hours after food was present. The fact that pain disappeared was no criterion that the ulcer had healed. A duodenal ulcer could only be recognised by sight, and it might not be palpable at all.

Professor H. ALEXIS THOMSON said that it was only seven years ago since the first operation for chronic duodenal ulcer was performed, and one had to be gradually educated to the difficulties of diagnosis and treatment, as had been the case with appendicitis. The sex preference in duodenal ulcer was remarkable, as it occurred in only 5 women to 50 males. The relationship to malignant disease was peculiar: a chronic gastric ulcer often became carcinomatous, but he doubted if anyone had seen this change in the case of duodenal ulcer. He always thought that if the pain was much influenced by diet, then the ulcer was likely to be gastric; while if any food might be taken with impunity, then it was probably duodenal. In cases of ruptured duodenal ulcer the best method of transport of the patient was in the sitting attitude. He had not thought it necessary to close the pylorus in operating.

Dr. J. O. AFFLECK said that his own experience was that the diagnosis of duodenal ulcer was difficult; the symptoms were often of a negative character, and the first might be those of perforation or hæmorrhage or they might be masked by the symptoms of other co-existing disease, as in one case the symptoms of advanced aortic disease entirely masked those of duodenal ulcer which was present. An infant who died after acute abdominal symptoms was found to have a perforated duodenal ulcer, and in the case of a woman who died there were 20 ulcers in the stomach and four in the duodenum. As to treatment, he did not think that all cases should be handed over to the surgeon. He had seen many cases of perfect recovery in patients who presented all the clinical symptoms of duodenal ulcer. One patient was too ill for operation and yet made a complete recovery; he had to state, however, that those cases dealt with by the surgeon had been eminently satisfactory.

Mr. HAROLD J. STILES said there were cases which on account of their aberrant symptoms he could not diagnose as cases of gall-stones with adhesions, malignant tumour of the hepatic flexure, &c. He was led to think that hæmatemesis or melæna were not very definite symptoms. He had met with two cases of vicious circle which had resulted from operation for a duodenal ulcer which did not exist. He was not in the habit of closing the duodenum when there was a definite ulcer, but only when there was gastroptosis. He would be chary in diagnosing acute duodenal ulcer, but if the symptoms pointed to it and if severe hæmorrhage were present he would advise operation. He was convinced that gastro-enterostomy did not do any harm to the patient, and young children developed quite as well as healthy children. As explaining the site of duodenal ulcer he said that it

might be due to the vascular distribution. The blood-supply up to a certain line was from the cœliac axis, while on the other side it came from the superior mesenteric artery; at the border-line between these, ulceration was likely to be found.

Dr. G. LOVELL GULLAND referred to the extreme difficulty in diagnosis, and said that hyperchlorhydria might be the only symptom present; two-thirds of his cases showed this condition, while one-third did not, and better results were obtained from medical treatment in the latter, while surgical measures were more satisfactory in the former. He thought that the following class of cases required operation: 1. All cases where there was retention of gastric contents owing to stricture. 2. All cases with severe and repeated hæmorrhage. In such cases examination of the fæces for the presence of blood was most useful. 3. All cases of inflammatory enlargement. 4. Patients who could not study their diet, as commercial travellers. He said that gastro-enterostomy was not entirely devoid of danger, while in many cases complete recovery did not take place, and the patient might be in as bad a condition as before operation.

The PRESIDENT said that some observers seemed to have had a large experience of duodenal ulcer, but this had not been his. Duodenal ulceration as seen post mortem or at operation was a very much less frequent occurrence than the evidence of the meeting might lead one to expect. In diagnosis he laid special stress on the sex question, and he required much greater evidence before diagnosing the condition in women. He had noted that cold made these cases much worse, and he had noted jaundice in cases of true duodenal ulcer. He alluded to hæmorrhage which might result from superficial erosions which might heal before operation, and hence difficulty would arise in determining from where the bleeding had proceeded. His own feeling as to operation was that if symptoms had occurred for the first time, medical treatment should be employed, but if the ulcer did not heal readily or if relapses occurred operation should be performed at once, as death so often followed on perforation or severe hæmorrhage.

Mr. D. P. D. WILKIE, Mr. ALEXANDER MILES, Mr. J. W. DOWDEN, and Dr. F. D. BOYD took part in the discussion, and in reply Professor CAIRD said that occult hæmorrhage would help them very greatly in diagnosis. In performing gastro-jejunostomy for duodenal ulcer there was an absolute assurance of cure. There was good reason to believe that a protective spasm did take place and that it was of great use after operation. It would be very difficult to decide the question by statistics because it was a question of individual cases. He knew of one case where a duodenal ulcer developed a year after an operation for appendicitis.

## ROYAL ACADEMY OF MEDICINE IN IRELAND.

### SECTION OF MEDICINE.

*Presentation of Cases.—Rheumatism in Childhood and in Adult Life.—Myasthenia Gravis.—Cerebral Tumour.*

A MEETING of this society was held on Feb. 10th, Sir JOHN W. MOORE, the President, being in the chair.

Dr. J. F. O'CARROLL showed a case of Athetosis in a schoolgirl, aged 9 years, who had had severe whooping-cough before the affection was noticed. He considered this had led to a cortical hæmorrhage into the right hand area of the brain, the athetosis resulting therefrom. Also a case of Occupation Neurosis in a barber, who exhibited weakness and choreiform movements in his right hand. Dr. O'Carroll considered the movements in the patient's hand were fatigue phenomena due to excessive use.—Dr. W. M. CROFTON discussed the share of toxins in producing the neuro-muscular condition in the second case, noting that the patient suffered from pyorrhœa alveolaris.

Dr. BOYD BARRETT read a paper on the Differences in the Manifestations of Rheumatism in Childhood and in Adult Life, in which he referred to the occurrence in children of rheumatic tonsillitis, chorea, "growing pains," rheumatic nodules, "stiff neck," and hip-joint affections of rheumatic origin, and cardiac trouble. Emphasis was laid on the absence of hyperpyrexia and the rare occurrence in children of early years of acute polyarthritis. He stated, in conclusion, that rheumatism in children was characterised by (1) the variety of its manifestations; (2) its insidious onset; and (3) the mildness of the arthritic symptoms and the corresponding severity of the cardiac trouble.—This paper gave rise to a lively discussion, in which the PRESIDENT, Dr. O'CARROLL, Dr. H. C. DRURY, Dr. J. M. DAY, and Sir W. J. THOMPSON took part.

Dr. T. GILLMAN MOORHEAD read a paper on Myasthenia Gravis, in which he summarised the various facts and theories connected with that disease and reported a case. There were well-marked bilateral ptosis, almost complete ophthalmoplegia, and drooping of the lower lip and lower jaw. The neck muscles were much atrophied. The myasthenia reaction was obtained. Death occurred quite suddenly ten days after admission to hospital. The necropsy showed a persistent, but not very large, thymus gland, nervous system normal, lymphorrhages very scarce and badly marked in the muscles, and some parenchymatous nephritis; other organs were normal.—Dr. CROFTON said he was much interested in the question of etiology raised by the condition of the thymus gland and the infiltration of the muscles with small round cells. He referred to a report which had been made of two cases of thymic asthma, in which there had been extremely flabby muscles and general muscular exhaustion, which were treated by X rays, and they got perfectly well; they lost their thymic asthma and their blood condition was restored to normal. He also referred to the effect of giving extracts of the sexual glands. The two lines of treatment might throw light on the condition of myasthenia gravis. First of all, X ray treatment of the thymus might be tried, then extracts of the testis might be given.—Dr. MOORHEAD said that in his case of myasthenia gravis he had hopes of being able to find an enlarged thymus, but there was no enlargement of the area of dulness on percussion, so he did not think X rays would be of use in that particular case. Dr. Henderson's researches had impressed him with the idea of working out the inter-relations between organs as regards the effect of certain obscure metabolic products. It might throw light on this case.

Dr. A. R. PARSONS, Dr. BENSON, Dr. J. T. WIGHAM, and Mr. G. T. JOHNSTON brought forward a case of Intracranial Tumour which was successfully localised in the right frontal lobe in the neighbourhood of the face and tongue centres. Mr. Johnston trephined over this region, and removed a hardened mass in three portions, which was handed to Dr. Wigham, who reported that the mass was syphilitic. The operation was followed by complete loss of power in the left arm and leg. His blood, tested by Wassermann's reaction, gave a positive result. He was discharged from hospital a little over two months after the operation in full possession of his mental and physical faculties except slight traces of optic neuritis in process of subsidence.—Dr. T. DONNELLY described two cases of a similar nature, in both of which cure seemed to follow the liberal administration of iodide of potassium.—Dr. G. E P. MELDON believed that iodide of potassium acted only in those cases which had been well treated with mercury.—Dr. PARSONS said that the patient had been given over 400 grains of iodide of potassium, but that, despite this, his condition had got steadily worse.

### SECTION OF OBSTETRICS.

*Presentation of Cases and Specimens.—Forty-six Cases of Wertheim's Operation.*

A MEETING of this section was held on Feb. 17th, Dr. H. JELLETT, the President, being in the chair.

The PRESIDENT showed a specimen of Adeno-carcinoma of the Cervix, taken from a middle-aged woman, which simulated a case of cervical myoma occurring in the same situation. There was nothing in the abdomen to be felt, and the diagnosis had to be made by splitting the cervix high up. The operation was a very extensive one.

Dr. GIBBON FITZGIBBON showed a case of Secondary Abdominal Pregnancy in the fourth month. The history was typical of ectopic gestation. The patient was aged 35 years, had two children, aged 9 and 7½ years. At the second confinement the child was very large, the presentation was a transverse one, and there was great difficulty in the delivery. Subsequently the patient evidently suffered from pelvic peritonitis or cellulitis. She had not been quite well for about five years after that, but

the two years previous to her admission to hospital she had been in fair health. She menstruated some time during last September. About Nov. 20th she was seized with severe pain in her abdomen and fainted. A few days after that she had profuse and continuous hæmorrhage which lasted for ten days, and intermittent hæmorrhage for a fortnight more. She went into hospital on Dec. 26th, but nothing could then be done. On Jan. 14th he opened the abdomen. The whole pelvic region was matted together. On taking out the tumour there was nothing between the fœtus and the intestines except the fœtal membranes. The front of the sac was formed by the anterior layer of the broad ligament. The uterus at the time of operation was of the size of a medium orange, and evidently contained a decidual formation, but no pieces were passed. The patient made an uninterrupted recovery, and went out on the twenty-sixth day after the operation.—Dr. R. D. PUREFOY wanted to know why Dr. Fitzgibbon had called it secondary abdominal gestation. Had Dr. Fitzgibbon ever read of primary abdominal gestation? He would like to know with what structures the placenta was continuous and on what structures the placenta had developed. There was a possibility of development of the decidua outside the cavity of the uterus.—The PRESIDENT said a case of primary abdominal pregnancy was recorded by Dr. Hurst. In this case the entire pregnancy structures were represented by a few layers of chorion.—Dr. FITZGIBBON said the entire pregnancy was closed up in an apparently closed sac. All through the abdomen there were pieces of very old brown leathery-looking blood clot which showed there had been bleeding into the abdominal cavity. The placenta was formed between the sides of the uterus running up over the top of the specimen. The rest of the placenta seemed to run over the top and front of the sac.

Mr. J. SPENCER SHEILL showed a Diseased Placenta. The patient was in the eighth month of her fourth pregnancy. The child was born dead. The pathological report by Dr. W. Boxwell was as follows: "The placenta is small, thin, and fibrous. On section it showed white areas of necrosis. Hæmorrhages are numerous, and there is a remarkable fibrosis of the blood-vessels, leading to more or less complete obliteration over considerable areas. The villi are atrophied." The diagnosis was probably syphilis, but syphilitic placentæ were said to be larger and paler.—Dr. E. H. TWEEDY said that small placentæ in syphilis were not uncommon, and were usually found with a dead fœtus, while in the large placenta the fœtus was usually born alive.—Dr. PUREFOY said that a syphilitic placenta associated with a dead infant was smaller than normal. In a syphilitic placenta the structural changes in the blood-vessels should enable one to diagnose the changes as syphilitic. Macroscopically he would be puzzled to say whether this placenta was not structurally deformed as a result of kidney disease.—Dr. W. M. CROFTON said as regards diagnosis it could be cleared up by doing a Wassermann.—Mr. SHEILL replied.

Dr. TWEEDY brought forward a series of 46 cases of Wertheim's Operation, with a mortality of 19·5 per cent. This percentage was swelled by the inclusion of his early cases, in which the mortality was 33 per cent. for his first year. He operated on 90 per cent. of the cases seen by him, and advocated operation in advanced cancer, not in the hope of bringing about a cure, but to mitigate pain and distress. The surgeon who could count a large percentage of cures after a two years' interval must have obtained them by selection of cases, and might, therefore, have consigned numbers of operable cancer patients to a hopeless outlook and a horrible death.—Professor W. G. SMITH said that Wertheim did well when he followed the general surgeon's method of removing the glands in operating on the breast. The operability of cases must be considered. The surgery of the ureter was of extreme importance. He described Dr. Latzko's method of implanting the ureter. The operation was a very simple one.—Dr. PUREFOY said the number of cases open to operative treatment had been enormously extended by Wertheim's method. Providing the patient was willing, operation should be attempted in any case where the patient was likely to survive the shock thereof.—Sir WILLIAM J. SMYLY said that Wertheim's method was still the best, and it would be best for beginners at least to stick closely to the rules laid down by him in a work just published founded upon an experience of 500 operations. The cause of ureteral fistula appeared to be still an unsolved riddle. Preparation of the patient before operation, he had read recently, was unnecessary, and only caused pain and hæmorrhage; but on thinking it over he thought it a great error to omit the preparation of the cervix, because should the vagina be opened the patient would undoubtedly get peritonitis.—The PRESIDENT said, with regard to the technique of the operation, there were two modifications—one, originally taught by Wertheim, in which the first step was to separate the bladder from the uterus; the other by Bumm, in which the infundibulo-pelvic ligament was divided, and the peritoneum at the base of the broad ligament cut through, after which the ureter was easily seen. It seemed to the speaker simple to find the ureter by this method, and it could then be traced into the cancerous mass. The only case where he thought this procedure was not preferable was where there was extensive involvement of the bladder wall, and this could be found out by cystoscopic examination.—Dr. TWEEDY, in reply, expressed surprise at the great number of cases of ureteral fistulæ and cystitis met with in Wertheim's cases, in spite of the most elaborate aseptic precautions and preparation of the patient. Preparation could be carried a great deal too far. An interval of two or three days should be the utmost to leave a patient without operating, as every hour was only adding to the chances of metastasis. In this operation especially gloves were required. If cancerous tissue got on the hands the bladder, ureter, and cellular tissue around the ureter might be infected, and he could quite understand cystitis and ureteral fistulæ occurring. Drainage of the cellular tissue was greatly advocated by Wertheim, but many great authorities hardly used drainage at all. Dr. Tweedy thought the great feature of Wertheim's operation was the complete shutting off of the peritoneum with drainage, and abdominal drainage was also at times a great advantage.

---

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on March 3rd, Dr. Phineas S. Abraham, the President, being in the chair.—Dr. Harold Pritchard read a paper on the Present Position of Vaccine Therapy. He said that bacterial vaccines had now become very generally recognised as valuable therapeutic measures in the treatment of infective processes. In the future they were probably destined to play a much more prominent part than now. A vaccine having been defined and its mode of action explained, the merits of the various methods of administration were entered into, preference being given to the subcutaneous method. It was pointed out that a slight local reaction was the end to be desired after an initial dose of vaccine; if the size of the subsequent doses was properly gauged, and the interval of administration carefully fixed, there ought to be no subsequent reaction. A general reaction should never be obtained. It was pointed out that a reaction depended on three factors: (1) size of dose; (2) virulence of vaccine; and (3) reaction of patient. The first factor was the only one which they had under complete control; so that it was impossible to lay down rules for the administration of vaccine which were applicable to every patient. Generally speaking, the more acute the case and the more general the infection, the smaller should be the dose. Many illustrative cases were quoted.—Dr. J. L. Bunch said that the immediate effects of treatment by vaccine could be more readily studied in diseases of the skin than in diseases of internal organs. One would not dream of asserting that every tuberculous, staphylococcal, or streptococcal skin disease could be cured by vaccine therapy, but their successes ought in the future to be greater than in the past. He did not himself feel inclined to dispense with opsonic estimation—the only method of estimating the antibacterial defences of the body at their disposal.—Mr. H. Wansey Bayly thought the method employed in the preparation of vaccines important. It was best not to expose them to a temperature above 55° C. Personally he did not use heat at all, but sterilised them with 1 per cent. carbolic in saline. He had seldom noticed either local or general reaction except with typhoid vaccines and occasionally gonococcal vaccines. He agreed that the opsonic index could not be considered a reliable method of estimating immunity or for controlling vaccine treatment. He agreed with Dr. Pritchard that gonococcal vaccines varied greatly in virulence, and

therefore the initial dose should be minimal. His experience of pneumococcal vaccine in the treatment of acute pneumonia, though limited, had been encouraging. He had, like Dr. Pritchard, not been successful in treatment of pyorrhœa alveolaris with vaccines, nor in acute gonorrhœa.—Mr. W. McAdam Eccles said that in many chronic affections the effects of vaccine were truly marvellous. For B. coli infections of the urinary tract vaccine therapy was very helpful.—The President said: "An authority once said in the future there would be no other method but vaccine treatment. Dr. Pritchard does not look at it as a panacea for all diseases, and has seen it produce an exacerbation. I am conservative both in politics and medicine. I admit it is an enormous advance. In my own experience many results have been the reverse of satisfactory. For instance, in acne, six of the worst cases I have seen have been made worse by vaccines; two of these are disfigured for life by the treatment. Acne can be cured by common-sense and rational treatment, external and internal. As regards boils, I fail to see why any case should be treated by vaccines. Many cases of boils treated by vaccines have recurred."—Dr. J. M. Bernstein, Dr. A. J. Rice-Oxley, Dr. H. Des Vœux, and Mr. Kenelm H. Digby also took part in the discussion.—Dr. Pritchard replied.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on March 1st, Mr. W. Morley Willis, the President, being in the chair.—Dr. J. W. Scott, in opening a discussion on General Anæsthetics, said that undoubtedly chloroform was the most dangerous anæsthetic employed, it having a death-rate of 1 in 3000. Surgical procedure played an important part in shock, especially if the patient were only partly under the influence of chloroform. It had been found that cases of death after chloroform contained a large percentage of acetone and diacetic acid in their urine. This acid poisoning occurred also in diabetes, acute yellow atrophy of the liver, and in phosphorus poisoning. As a prophylactic against chloroform fatality it was advisable to prepare the patients by giving glucose, avoiding prolonged fasting, by washing out the rectum and giving bicarbonate of soda and glucose to those patients whose urine contained acetone and diacetic acid. As regards ether, it was more difficult to administer, safer in its immediate effect, but very often led to serious pulmonary complications. The open method was the best method of administering it, and he had used it frequently in children without causing any bronchitis. A mixture of chloroform and ether was the most satisfactory of all, as it maintained a more constant blood pressure.—Dr. R. Alderson said the death-rate of chloroform was 1 in 2500, that of C.E 1 in 5000, and of ether alone 1 in 13,000. Therefore chloroform must be the most dangerous method. He advised the members not to limit themselves to one anæsthetic. He preferred giving a mixture of ether and chloroform by the open method. This did away with all the objections of a Clover and rendered the patient less liable to post-anæsthetic vomiting. The mixture should be slowly given. The chief objections to the open method of giving ether were: (1) the long induction period; (2) the difficulty of obtaining complete muscular relaxation; (3) the difficulty of getting some patients under its influence; and (4) the liability to subsequent chest complaints. He should advise ether to be always given for minor operations.—Dr. Amelia M. Le Pelley, remarking that emergency cases took anæsthetics well, thought the ordinary preparation of patients was too drastic; operations should be performed, when possible, in the morning and fright reduced as far as possible. As a rule the temperature of the operating room was too high. As the ordinary reflexes varied so much with different patients she paid most attention to the breathing.—Mr. Kenneth Black said that he had seen 30 patients die on the operating table—23 of these after chloroform. In all cases the cause of death was an overdose of the anæsthetic, some, of course, being more susceptible than others. He noticed that the special anæsthetists had a much smaller mortality. Most of the recorded fatalities occurred in institutions where the death was always followed by an inquest; he was quite sure that in general practice many deaths were unrecorded.—Mr. T. B. Gilbart-Smith always started anæsthesia with A.C.E. mixture and generally continued with chloroform. In abdominal operations the patients stood the operation better if they were deeply under.—Dr. J. A. Waring preferred A.C.E., and believed in giving as little as possible. He found heart disease no hindrance to giving an anæsthetic if it was administered slowly and carefully.—Mr. R. G. Hogarth preferred to have ether administered by the open method, but mentioned one case which was followed by acute bronchitis.—Mr. R. Wood (Ilkeston) always gave chloroform in midwifery cases with success.—Dr. W. Hunter preferred A.C.E. and regarded chloroform as most dangerous. He thought that the services of newly qualified assistant house surgeons were wrongly employed.—Mr. H. Bell Tawse said that chloroform was the only satisfactory anæsthetic in nasal cases. Ether caused too much hæmorrhage and mucus formation.—The President thought that chloroform was perfectly safe in the hands of skilled men. It certainly was quite pleasant to take and produced the best results from a surgeon's point of view.—Dr. Scott and Dr. Alderson briefly replied.

THE NEW LONDON DERMATOLOGICAL SOCIETY.—A meeting of this society was held at 49, Berners-street, W., on March 9th, Dr. P. S. Abraham, the President, being in the chair.—Mr. Dennis Vinrace showed a man with Cicatricial Alopecia simulating Alopecia Præmatura.—Dr. Tom Robinson showed a man, aged 46 years, with Tubercular Lupus of the Back of the Hand, resulting from an injury 26 years previously.—Dr. David Walsh showed a little girl aged 9 years with Dermatitis Herpetiformis of three months' duration, a similar attack having occurred two years ago.—Dr. Morgan Dockrell showed: (1) A young woman, aged 19 years, with Bazin's Disease of four years' duration; and (2) a case of Ulerythema of the Scalp in a man aged 31 years; the left ear was also slightly affected.—Dr. W. Knowsley Sibley showed: 1. A woman, aged 31 years, with Erythema Bullosum. The attacks commenced at the age of 8 years, and the present one was widespread, many of the older lesions being scarred and slightly pigmented. 2. A case of Psoriasis in a man aged 38 years in which the mucous surface of the glans penis was affected, in addition to other parts of the body.—Dr. W. Griffith showed: 1. For Dr. M. K. Hargreaves, a woman, aged 25 years, of English nationality, with extensive Favus of the Scalp and Trunk which had existed since infancy. Much improvement had taken place from X ray treatment. 2. The young man shown at the previous meeting of the society with Mycosis Fungoides, to illustrate the improvement as a result of X ray treatment. The diagnosis had been confirmed microscopically.—Dr. G. Norman Meachen showed: 1. A Jewess with Ulerythema of the Scalp of four years' duration. 2. A case of Papulo-necrotic Tuberculides in a young woman, aged 30 years, affecting the legs and also the backs of the hands, where the condition was typically that described as folliclis.

CHILDREN'S HOSPITAL, BIRMINGHAM. — The management committee reports that the number of patients treated during 1910 was 15,261, as against 15,240 in 1909. The past year would always be remembered with gratitude by reason of the opening of a King Edward VII. Memorial Fund by the proprietors of the *Birmingham Daily Mail*, who decided to devote the proceeds to the erection of a statue in memory of the late King, and to place the balance at the disposal of the children's hospital committee. It was hoped that the amount would reach £30,000. Had it not been for this the future of the hospital would have been a source of great anxiety with the present lease expiring and very little prospect of sufficient funds being raised in time to erect new buildings elsewhere. The plans of the new hospital were not finally settled. The open-air treatment which it was hoped to make a special feature of the hospital involved the planning of the building on novel lines, and improvements in design and arrangement continually suggested themselves. It was hoped that the actual building operations would be commenced in the spring of next year. The accounts for the year showed a deficiency of £12 as compared with £466 for the preceding year. To this current deficiency had to be added the accumulated deficiency of £605 brought forward from last year, making £617 to carry forward. Operations on in-patients numbered 378, and on out-patients 2558, the latter being an increase of 483 on the previous year. There were 143 deaths among in-patients, giving a death-rate of 14·54 per cent.

# Reviews and Notices of Books.

*The Principles of Gynæcology.* By W. BLAIR BELL, M.D., B.S. Lond., Assistant Gynæcological Surgeon, Royal Infirmary, Liverpool. With 6 coloured plates and 357 illustrations in the text. London: Longmans, Green, and Co. 1910. Pp. 551. Price 21*s*.

IN writing this work the author has endeavoured to present a complete and modern survey of the foundations on which gynæcology is established. We may say at once that he has succeeded very well and has written a concise and readable text-book of much merit. It is drawn up on a simple and logical arrangement which certainly gives, as Dr. Blair Bell claims, greater lucidity and more consecutive reading than the classification usually adopted.

The first chapter contains a short but interesting account of the evolution of the female genital organs, and is followed by a good description of the anatomy of these organs. We notice that the author is in favour of the view, the wrong one in our opinion, that the cells of the membrana granulosa are derived from the stroma of the ovary. We have little doubt that the conclusions of Waldeyer, Schäfer, Nagel, and Van Winiwarter are correct, and that they are right in maintaining that these cells and the interstitial cells are in reality derived from the germinal epithelium of the ovary. This view finds acceptance from the great majority of modern workers, and to us this mode of origin appears much more consistent with the theory that the interstitial cells play an important part in the production of the internal secretion of the ovary. In the chapter dealing with the physiology of menstruation Dr. Blair Bell puts forward his view that the calcium metabolism of the body is largely concerned in the production of this function, and that the ductless glands also play an important part in the genital functions and in controlling the calcium metabolism.

After a chapter on the methods of examination of the pelvic organs, which is well arranged, a section is devoted to the congenital derangements of the normal anatomical conditions, followed by one on the acquired derangements. The method employed by the author of introducing a Hodge or ring pessary is not, in our opinion, the best, since it necessitates the introduction into the vagina of the index finger as well as the pessary—a needless complication. It is a pity that nothing is said as to the mode of action of a Hodge pessary, as this is a point on which much confusion exists among students. With the recommendation that the abdomen should be opened in cases where the gravid retroverted uterus is impacted, and replacement is impossible, we disagree. It is the usual experience in these cases that no such treatment is necessitated. In the section dealing with the treatment of chronic inversion of the uterus nothing is said of hysterotomy by the vagina instead of abdominal section.

In discussing the complications of fibromyomata uteri the statement is made that these tumours tend to produce relative or absolute sterility. This is very far from being proved, as in the majority of cases the sterility precedes the development of the fibroid tumours, and cannot therefore be caused by it. How does Dr. Blair Bell determine that there is no room in the abdomen for the development of a fœtus when large fibroids are also present? The softening that these tumours undergo during pregnancy is often so marked that it is most difficult to say to what extent they will or will not yield and give way to the developing fœtus. In the operative treatment of cases of retroversion of the uterus Gilliam's operation of drawing the round ligaments into the abdominal wall, and fixing them there, is strongly recommended, and according to the author gives good results. The section dealing with the main principles of gynæcological operations is a good one, and there is no unnecessary detail. In the two appendices, Electro-therapeutics in Gynæcology, contributed by Dr. Curtis Webb, is considered in the first, and in the second a useful classification of the causes of certain symptoms is given.

The book, as we have said, is a good one, and if we have devoted some space to what we consider its shortcomings, we are none the less aware of its merits. The author lays rather too much stress upon the quite unproved theory of the great importance of the calcium content of the blood, and the large part played by the secretions of the ductless glands in the causation of certain gynæcological conditions, but the lapse of time will prove or disprove the correctness of his views. The work is carefully printed, the index is accurate, and the illustrations are well reproduced. In the figure on p. 82, giving the levels of the fundus uteri at the different months of pregnancy, it is a pity the author has not relied on his own observations instead of copying the illustration from another book, and adopting the average positions as given by Whitridge Williams in his text-book of midwifery, as they are certainly inaccurate.

---

*Appendicitis and other Diseases of the Vermiform Appendix.* By HOWARD A. KELLY, M.D. With 215 original illustrations, some in colours, and 3 lithographic plates. London and Philadelphia: J. B. Lippincott Company. 1909. Pp. 502. Price 25*s*.

A FEW years ago we reviewed a very elaborate work on the vermiform appendix which Dr. Kelly wrote in conjunction with Dr. Herdon. This formed a storehouse of facts and information relating to this organ, but we felt while reading it that a smaller work would prove more widely useful, and therefore are glad that the present work has been prepared. Not that the present volume is small, but it is decidedly less voluminous than its predecessor. After an interesting chapter on the history of our knowledge of the diseases of the appendix its anatomy is considered. Diagrams are given illustrating almost every conceivable part of the subject, and especially good are the illustrations showing the vascular supply of the organ. The bacteriology is next described and the more important organisms are discussed fully. The pathological section is very complete and the various affections from which the appendix may suffer are described. As to the etiology, Dr. Kelly tells us that he is acquainted with several instances in which an appendicitis was apparently promoted by the attachment of the appendix to the site of a previous operation. The disease appears to be rare amongst the negro race. Dr. Kelly considers disorders of digestion to be the most common exciting causes, and trauma is another factor which he looks upon as important. He agrees with all other observers in considering the presence of foreign bodies in the appendix a very rare cause indeed. In almost a thousand cases of appendicitis in the Johns Hopkins Hospital foreign bodies were found only in four instances. The clinical history and the diagnosis are then described. A valuable account is given of the leucocytes in appendicitis; Dr. Kelly lays very great stress on a differential count, and he considers an increase of the neutrophiles important, especially if associated with a decrease of the eosinophiles.

As to the treatment previously to operation, we are told that it is a good plan, if operation cannot be immediate, to give the patient just enough opium to relieve pain and afford a little ease. We agree that opium may be of use, but we think it would have been as well to mention that it is inadvisable to give opium before the case is seen by the surgeon who may have to operate. Opium may have a disastrous effect in masking the symptoms. We concur with

Dr. Kelly when he states that the ideal time for operation in acute appendicitis is within the first few hours after the appearance of symptoms, but unfortunately it is very exceptional for the surgeon who may have to operate to see a case in this period.

We need not follow the author through the descriptions of the operation. The various incisions which have been recommended are given, and in the case of each Dr. Kelly mentions its special field of usefulness. The chapter on post-operative sequelæ is good, and we may also mention with special approval the account of the relation between appendicitis and gynæcological affections. The chapter on the medico-legal aspects of appendicitis is necessary nowadays, when compensation arising for injuries received by workmen in the course of their employment is enforced by law. In this connexion the question of the relation of trauma and appendicitis deserves special attention.

We appreciate the extensive index of names, though we may point out that as a rule it is far better to have only one index to a book, but if necessary the different classes of items included in it may be distinguished by the employment of different forms of type.

---

*A Treatise on Materia Medica and Therapeutics, including Pharmacy, Dispensing, Pharmacology, and Administration of Drugs.* By RAKHALDAS GHOSH, L.M.S., Calcutta University, Lecturer on Materia Medica, Calcutta Medical School. Edited by J. T. CALVERT, M.B. Lond., M.R.C.P. Lond., Lieutenant-Colonel I.M.S., Professor of Materia Medica and Therapeutics, Medical College of Bengal, &c. Fourth edition. Calcutta: Hilton and Co. 1910. Pp. 742. Price, rupees 5, or 7*s.* 6*d.*

A TREATISE on materia medica must from its nature be largely a compilation, and its value will be in proportion to the care and time expended in its preparation. Judged by this standard, Mr. Ghosh's book is a remarkable one, and bears striking testimony to the arduous and assiduous labours of its author. Previous editions have been edited by Lieutenant-Colonel Lukis, I.M.S., owing to the death of Mr. Ghosh, but this, the fourth edition, has been revised and edited by Lieutenant-Colonel Calvert, who acknowledges in the preface the help afforded him by Dr. B. N. Ghosh, the son of the author. The book is divided into seven parts, of which the first is devoted to materia medica proper. The general characters of drugs are described, their composition and impurities are discussed, and the various pharmacopœial and non-official preparations are tabulated, with their composition, strength, and doses when used internally. The second part deals with pharmacy and dispensing, the third with the methods of administration of drugs. Both of these abound in useful practical hints and valuable suggestions, difficulties in dispensing and pitfalls in prescribing being carefully indicated. The general pharmacology of medicinal substances forms the subject of the fourth part, in which drugs are classified according to their actions upon the different systems and organs of the body, drugs with a similar action being arranged in tables.

The major part of the book is occupied by a detailed consideration of the official remedies, including those in the Indian and Colonial Addendum to the Pharmacopœia, and of many unofficial ones. Their nature, source, general characters, official and non-official preparations, and doses are given, and then their pharmacology and therapeutics are discussed. In the case of drugs of Indian origin their names in the various Indian languages are given. Under the heading of therapeutics the chief uses of the drugs are indicated, and frequently prescribing hints are added in regard to the best methods of administration and sometimes actual prescriptions. The drugs in this section are considered in alphabetical order. The general principles of serum therapeutics and of treatment by vaccines form the subjects of a special section, in which all the chief methods of protective and curative treatment by these substances are discussed. The various applications of organotherapy are also described. A full and convenient index is appended.

Mr. Ghosh's book is a most useful work of reference, and as the material is well arranged, and the information given is generally reliable, it should prove of value to the practitioner as well as to the student.

---

*Outlines of Zoology.* By J. ARTHUR THOMSON, M.A. Fifth edition. Edinburgh, Glasgow, and London: Henry Frowde and Hodder and Stoughton. 1910. Pp. 855. Price 12*s.* 6*d.*

THE above edition of this well-known text-book is rather more than 200 pages longer than the first edition, which appeared in the year 1892. From this increase, which is obviously very great, we can measure in some degree the extremely rapid advance of zoological science in the last 18 years. For the scope of the work has not changed in any respects and about the same ground is covered. The vast increase of knowledge of fact has, however, compelled the author to extend his accounts of the various groups of animals at the expense of the more general parts of the treatise, and it is not without interest to observe the proportions which the classes and orders of the animal kingdom bear to each other in the present and in the first edition of this handbook. We find on a comparison of the space devoted by Professor Arthur Thomson to individual groups that the sections devoted to the protozoa, sponges, coelenterates, and worms have on the whole undergone the most considerable increase, a result which entirely harmonises with the progress of recent research. And among the vertebrated animals the account of the fishes is proportionately longer than that of any other group. It is not, of course, possible to base any very accurate statistics upon this summary comparison, but, on the whole, the author appears to us to be expressing the relative importance at the present time as compared with the past of these different orders of invertebrates and vertebrates. Moreover, Professor Thomson is engaged in the instruction of medical and zoological students at the University of Aberdeen, and is not likely from the nature of his avocations to be prejudiced in favour of this group or of that, as might be the zoologist who is only devoted to his own investigations.

It is something of a *tour de force* nowadays to cope with the anatomy of the whole animal department of nature in one volume. To conduct to a successful issue so large an undertaking needs a man fitted, as was said of Dr. Johnson, to grapple with whole libraries. A professor of zoology is really the only person who can, without excessive nervousness, undertake such a task. For in these days of possibly over-examination he has before his eyes the constant fear of "external" examiners, keen to note the deficiencies of his pupils in the most recently acquired knowledge. For the zoologist whose life is mainly spent in research it is not expedient that he should write a general text-book. Though his knowledge of some branch or branches is no doubt both vast and minute its depth shallows rapidly at the boundaries of the field of his own researches. We find, in fact, that Professor Thomson has evidently at his fingers' ends the main facts of zoology, and we have been at pains to test a large number of his statements. Among these there are one or two with which we do not agree. For example, the author

says of the bird that "the two valves between the right auricle and the right ventricle are in part muscular." This phrase seems to us to be misleading. There is but one flap to the valve, which is entirely muscular, and which only surrounds half of the atrioventricular orifice. The figure of the genitalia of the earthworm used is the well-known figure of Hering. But this figure is incomplete in that the receptaculum ovorum is not shown therein, though it must be added that the author has duly mentioned this structure in the text. There is a misleading sentence in the definition of the tapeworms, where these animals are said to possess "hooks, grooves, or suckers," the implication being that only one of these means of attachment is present. This is, of course, an error if it is read literally. But, as has been already implied, the misleading statements are not conspicuous, and the book may be recommended as trustworthy.

---

*Thérapeutique Usuelle du Praticien.* By Dr. ALBERT ROBIN, Professor of Clinical Therapeutics in the Faculty of Medicine, Paris. Paris: Vigot Frères. 1910. Pp. 520. Price 8 francs.

A MORE comprehensive title of this large volume would be "Clinical Therapeutics." Dr. Robin has selected certain morbid conditions which yield more or less readily to systematic treatment and examines at length the general considerations which should determine the therapeutic measures to be adopted, and then explains in detail how these measures should be applied. He discusses many diseases of the stomach and intestines, including atonic dyspepsia, chronic gastritis, gastric ulcer, and mucous colitis. He records certain cases characteristic of the condition he is describing, and builds up his remarks on the progress which ensued. Under the heading of diseases of the liver he debates the treatment of cirrhosis of the liver. In speaking of the management of the diet in cirrhosis of the liver he expresses a favourable opinion of the employment of skimmed milk as a sedative to hepatic activity. The treatment of chronic nephritis, of arterio-sclerosis, and of certain nervous affections, e.g., facial neuralgia, and of psychical conditions of digestive origin is also described. The work cannot be regarded as a text-book, but is rather a series of articles on the treatment of separate maladies, of some interest to general practitioners, for whom it is mainly intended.

---

## LIBRARY TABLE.

*Medizinal-Berichte über die Deutschen Schutzgebiete für das Jahr 1908-09. (Medical Reports upon the German Protectorates for the Year 1908-09.)* With 35 illustrations in the text, 2 maps, and 39 reproductions of photographs. Berlin: Published for the Imperial Colonial Office by Ernst Siegfried Mittler and Son. 1910. Pp. 522. Price, paper boards, 9 marks; bound, 10 marks.—This volume contains reports for the fiscal year ended March 31st, 1909, upon the medical and sanitary administration of Germany's eight protectorates—namely, German East Africa, the Cameroons, Togoland, German South-West Africa, New Guinea, the Caroline Islands, the Marshall Islands, and Samoa. Particulars are given of the medical and sanitary staff serving in each colony, and the hospitals provided for Europeans and for natives are described. Incidence of disease and the mortality from various causes are fully considered, tabular statements being given for each protectorate. Special attention is devoted to communicable diseases spread by infection, like small-pox, and also to those transmitted by the agency of insects, more especially malaria and sleeping sickness. The African colonies from their importance naturally occupy a considerable portion of the space, extending, indeed, to nearly three-fourths of the volume. The diseases of animals, particularly those due to biting insects, are dealt with from the veterinary point of view in some detail. In the African protectorates the subject of sleeping sickness receives due attention. The special report on Trypanosomiasis in East Africa is furnished by Professor Kleine, formerly a member of the German Sleeping Sickness Commission (of which Professor R. Koch was the chief), whose notable experimental work on the infectivity of the glossina palpalis is well known. The reporter on this disease in Togoland is Dr. Zupitza, who gives an account of the work done in that protectorate by the German Commission, and in it he describes the organisation of the campaign against the disease in Togoland, the distribution of the malady and of the glossina palpalis as well as of other tsetse flies in that colony. He discusses the reasons for the hitherto limited diffusion of sleeping sickness in the protectorate and the danger of extension of the infection in the near future. He also describes the measures taken against the fly and for preventing the importation of infection from without. A description is added of the sleeping sickness camps established for the treatment of natives suffering from the disease. After the reports is given a list of the papers published during the year on tropical medicine and veterinary science by the members of the Government medical and veterinary staff, as also by the surgeons attached to the native troops. In the appendix are also given reports on the health of the troops employed in German East Africa and in the Cameroons for the fiscal year 1907–08. The volume contains a considerable amount of information, not only as to diseases in the tropics, but also as to sanitary administration among native populations. The book is plentifully illustrated by sketches, maps, charts, and photographs; there is much in it that is highly interesting and instructive.

*The Medical Examination of the School Child.* By D. A. CARRUTHERS, M.D. Edin., D.P.H., Education Medical Officer to the County of Buckingham, &c. London: Office of *The Medical Officer*. 1910. Pp. 91. Price 2*s.* 6*d.* net.—This is a handy reprint of articles written originally on request to summarise the conditions of which the school medical officer should take cognizance. Naturally, therefore, the schedule of medical inspection issued by the Board of Education is followed. The author very properly lays stress on the importance of cleanliness of the teeth, and combats the opposition that he seems to have found on the part of "some medical practitioners who consider it is a mistake to clean the teeth of children in elementary schools or to give them directions for so doing." The articles are necessarily somewhat sketchy, and a fuller index is desirable; but the book will prove useful to school medical officers.

*Allergie.* Von Dr. CLEMENS FRH. VON PIRQUET, Professor der Kinderheilkunde an der Universität Breslau. 30 illustrations. Berlin: Julius Springer. 1910. Pp. 96. Price M.3.60.—It is well known that persons who have suffered from measles, small-pox, or whooping-cough are not usually again affected by the same disease. They are said to be immune. On the other hand, some diseases, like pneumonia and erysipelas, are apt to leave an increased susceptibility to the recurrence of these maladies. This subject, so far, has attracted the attention chiefly of the experimental pathologists. The author has coined the word "Allergie"—not a happy combination—for the clinical picture of this changed reaction—increase or decrease of susceptibility. Richet coined the word anaphylaxy for increased susceptibility. The author in the special part of the memoir gives cases of "serum disease"—by which term he indicates a condition in which a second dose of a serum increases the susceptibility to the serum, either in animals or man. There may, however, be the opposite condition of diminished susceptibility. Leaving experimental pathology, he proceeds to deal

with urticaria, hay-fever, vaccines, and variola, measles, tuberculosis, syphilis, diphtheria and many other diseases in their relation to the injection of various sera. It is an interesting little monograph, based on the author's experience, which should prove useful both to the dermatologist and the physician. The bibliography extends to 272 references to papers dealing with this "change of reaction."

*Childhood.* Edited by T. N. KELYNACK, M.D. Vict. London: Charles H. Kelly. 1910. Pp. 152. Price 1*s.* net.—This is the second of a series of National Health Manuals, presenting to those interested or engaged in social service special aspects of personal, domestic, or national well-being in non-technical language. It is recognised that social reform is still in an experimental stage. After an introduction on Childhood by the editor the following subjects are considered: the Growth of Children, by Dr. G. F. Still; the Psychology of Childhood, by Dr. W. B. Drummond; the Hygiene of Child Life, by Dr. Leonard Findlay; A Child's Diet, by Dr. J. G. Emanuel; the Preventable Diseases of Childhood, by Dr. John McCaw; Tuberculosis in Childhood, by Dr. Clive Rivière; Alcoholism and Childhood, by Dr. G. Basil Price; Dependent Children, by Dr. Frances M. Dickinson Berry; Prevention of Cruelty to Children, by Dr. T. Eustace Hill; Legal Protection of Childhood, by Mr. Digby Cotes-Preedy; and Moral Health of the Child, by Dr. Mary Scharlieb. The appendices contain bibliographies classified according to each subject. The chapter on the moral health of the child particularly contains much that though in no wise new is lamentably overlooked by too many on whom the task of the bringing up of children devolves.

## ROYAL COLLEGE OF SURGEONS OF ENGLAND.

### MEETING OF COUNCIL.

AN ordinary meeting of the Council was held on March 9th, Mr. BUTLIN, the President, being in the chair.

In accordance with the recommendation from the Board of Examiners in Dental Surgery it was resolved that the first professional examination for the Licence in Dental Surgery shall consist of two parts—Part I., Mechanical Dentistry, and Part II., Dental Metallurgy, and that these parts may be taken together or separately.

A report was received from the museum and finance committees in which it was recommended that the specimens illustrating general pathology be exhibited on the ground floor of Room III. of the museum, and that the librarian's old house be reconstructed to provide additional accommodation. The report was approved and adopted.

A letter was read from Mr. C. H. Golding-Bird, the representative of the College on the Central Midwives Board, reporting the proceedings of that Board during 1910. The best thanks of the Council were given to Mr. Golding-Bird for his services as the representative of the College.

The PRESIDENT reported the delivery of the Hunterian Oration by Mr. Edmund Owen on Feb. 14th, and it was resolved that the best thanks of the Council be given to Mr. Owen for his oration, and he was requested to publish it.

The PRESIDENT reported the delivery of the various lectures—Hunterian Lectures and the Arris and Gale Lecture. After much discussion it was resolved—

That, as it has been found to be impossible to proceed with the suggestion adopted by this College for combined examinations for medical degrees by the Royal Colleges and the University, the Council do not lay any detailed proposals before the Royal Commission, but instruct their delegates, besides stating their individual views, to point out:—

1. The disability under which London medical students are placed owing to the difficulty of obtaining degrees in the Faculty of Medicine of the University, a disability not experienced in other parts of the United Kingdom.
2. The action taken by this College in the past with the object of removing this disability.
3. Its continued willingness to coöperate in any scheme for making the degrees in the Faculty of Medicine more accessible to London medical students.

The delegates are Mr. Butlin, Sir Henry Morris, and Sir Alfred Pearce Gould.

# New Inventions.

## A VAGINAL GUIDE FOR HYSTERECTOMY.

IN the performance of total hysterectomy it is often of value to be able accurately to define the limits of the vagina, and I have found the instrument here described of service.

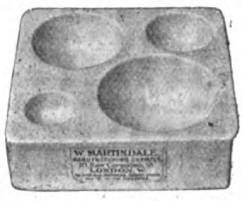
$\frac{1}{3}$ Sc

A straight handle, 10 inches in length, carries at one end a flat piece slightly curved like the end of a duckbill speculum which fits the vaginal fornix. After cleansing the vagina this is introduced into the anterior fornix. When the broad ligaments have been ligatured and divided the nurse or third assistant pushes the instrument upwards and the vaginal limits are at once well defined. After ligaturing the uterine arteries the anterior vaginal wall is divided upon the flat surface, this giving a firm base upon which to cut. The assistant then turns the instrument into the posterior fornix and the posterior vaginal wall is similarly defined and divided. I have found this manœuvre of assistance not only in defining the position of the vaginal incision but in shortening the time expended in determining the extent of tissue to be removed. It is equally useful if the incision is made by the cautery, as the metal plate allows one to burn through the vaginal wall with confidence that no underlying parts will be injured. With reference to the possibility of infecting the abdominal wound when the cancerous uterus is removed, I think this would be obviated by the following procedure. Before the operation begins a heavy tenaculum is placed on the cervix. As soon as the uterus is freed from its connexions, the organ is withdrawn per vaginam, unless, of course, of a very large size. This will obviate the necessity of curetting and closing the mouth of the uterus and save a certain amount of valuable time. The instrument is supplied by Messrs. Down Bros., of St. Thomas's-street, London, S.E.

P. CLENNELL FENWICK, M.D. N.Z., F.R.C.S. Edin.
Christchurch, New Zealand.

## A COMBINED PORCELAIN SOLUTION TRAY, STAINING BATH, AND EMBEDDING MOULD.

I HAVE designed this tray for use as a temporary receptacle for different solutions during minor operations. By reason of its stability, cleanliness, shape, and size it is specially adapted for the consulting-room table of all practitioners, especially those engaged in aural, nasal, laryngeal, ophthalmic, gynæcological, or dental work. Its use will be found to economise the employment of cocaine, adrenalin, and other costly solutions, while it is readily cleaned and cannot be upset. It is specially useful in preparing "606" for syringe injection, and to pathologists for embedding tissue of all sizes either in paraffin or celloidin, while the same time it affords excellent staining baths for sections. The cells should be wiped out with a very thin film of vaseline before embedding tissues. These wells are of 3, 5, 15 and 20 c.c. capacity, which experience has proved to be the most convenient sizes for the different purposes for which they may be employed. The dish can be obtained from Messrs. W. Martindale of 10, New Cavendish-street, W.



WYATT WINGRAVE, M.D. Durh.
Chenies-street, W.C.

DEVON AND EXETER DENTAL HOSPITAL.—Mrs. Nosworthy of Dawlish (Devon) has given £500 to the Devon and Exeter Dental Hospital. This makes a total of £3000 which Mrs. Nosworthy has given to this charity during the last few years.

# THE LANCET.

*LONDON: SATURDAY, MARCH 18, 1911.*

## The Problem of Sunday Entertainments and the Metropolitan Hospital Sunday Fund.

As will be known to most of our readers from articles in the daily press, or as may be learned from a report in this issue of THE LANCET, a serious division of opinion was witnessed at a meeting of the Council of the Metropolitan Hospital Sunday Fund held at the Mansion House on Friday in last week. The gathering of the Council, which was presided over by the LORD MAYOR, was a strong one, and the principal reason for the meeting was the fact that the attitude of certain hospitals in associating themselves with cinematograph entertainments held on Sunday, and benefiting by the receipts, had come to the unfavourable attention of some supporters of the Fund. There were members of the Council of the Fund, both clerical and lay, who held such association to be inadvisable on various grounds, while certain leading churches, Nonconformist as well as Church of England, had signified their feeling in the matter in an unmistakeable way by asking permission to allocate their contributions definitely to those hospitals which were not deriving profit from these shows. The matter had been considered previously by the General Purposes Committee of the Fund, whose attitude was shown by a recommendation to the Council to adopt a resolution disapproving of hospitals, while receiving grants from the Fund, being concerned in any movement "contrary to the spirit of its supporters," and suggesting the penalising such hospitals at the next distribution of awards, if any diminution in the receipts of the Fund seem attributable to Sunday shows. It is clear that the decision of the Council must depend largely upon the interpretation put upon the ambiguous phrase quoted, for the spirit of a movement can seldom be exactly defined.

Archdeacon SINCLAIR moved the adoption by the Council of the views and recommendations of the General Purposes Committee, although he disclaimed any intention of condemning in the name of the Fund the establishment of Sunday theatrical shows at the various cinematograph establishments. Archdeacon SINCLAIR'S speech was made from the point of view that the integrity of the Fund would be impaired and possibly its future endangered by not dealing with a situation, on which there were avowedly great difference of opinion, in the manner indicated in his resolution. He pointed out that among the supporters of the Fund there were people who objected to the holding of these entertainments on Sunday, either because they considered them to be an evasion of the law or because they objected to such entertainments being held on the day of rest. He considered that for the salvation of the Fund it was necessary to appease the apprehensions of this large section of its supporters by registering formal disapproval of any hospitals receiving grants from the Fund while they are concerned in a movement which had caused a scandal among some of their constituents. Archdeacon SINCLAIR put forward his views, and those of the General Purposes Committee, as might have been expected from him, with no narrow Sabbatarianism; as far as was possible for a distinguished clergyman, he backed up the recommendation of the General Purposes Committee from the point of view of expediency. The same may be said of his main supporter, Sir ALFRED PEARCE GOULD, who held that the action of those hospitals which were interested in these shows and received money therefrom was perilous, in that a charity which can trade for profit may lose certain of its eleemosynary support. Mr. SYDNEY HOLLAND moved an amendment that the Council of the Fund should take no action in the matter, and his vigorous speech showed how deep is the difference of opinion on the Council on the matter, a fact which furnishes obvious reasons why the Council should not attempt to come to any decision at all in a hurry. Like Archdeacon SINCLAIR, Mr. HOLLAND also spoke largely from the point of view of expediency, believing that the recommendation, which aimed at consolidating the Fund by speaking in behalf of the spirit of the foundation, was certain to act in the exactly opposite manner and to alienate, in a degree which might be disastrous to the Fund, the goodwill of the public by which the Fund exists. He admitted that the London Hospital, of which he is chairman, received a large annual sum from Sunday entertainments, and considered that it was no business whatever of the Metropolitan Hospital Sunday Fund to attempt to dictate to any charity what should be the sources of its receipts by threatening to consider such sources when making the annual awards. Mr. HOLLAND was immediately found to be quite right in believing that the recommendation of the General Purposes Committee had behind it no solidarity of opinion, for two well-known clergymen, the Rev. H. R. GAMBLE and the Rev. C. H. GRUNDY, seconded and supported his amendment, thereby showing that some clergymen considered that money obtained from Sunday cinematograph shows had not an origin so discreditable as to make it necessary for the Council to punish by any system of fines those charitable institutions which benefited thereby.

An interesting debate led, as will be seen by our report, to the adoption in the first instance of the recommendation of the General Purposes Committee, but it was agreed to refer the matter back to the General Purposes Committee, so that Mr. SYDNEY HOLLAND, who had previously been, through some blunder, deprived of the opportunity, should be able to place his views in detail before the committee. We trust that the committee will think very seriously before forcing the Council to action upon this matter. A very serious situation has arisen in one of the most important of the metropolitan charities, a charity the good work and success of which we have always had deeply at heart, and an ill-considered movement may do serious damage. It must be admitted at once that those responsible for the Fund are in a very difficult situation. No course that they can possibly take will please all their

constituents; the Fund is dependent upon the public, mainly through the churches, for its support, and if the public is not satisfied with the way in which the Fund is administered it will cease to subscribe. How far can the Council allow itself to be swayed by such a situation? Where does honest administration, having regard to the spirit of the foundation, end, and where does mere opportunism begin? We believe that if these questions are faced, the answer will be found different to the one which the Council last week was prepared to give. We are perfectly certain that there are just as many good clergymen and honest observers of religious tenets who are for as who are against the holding of public entertainments on Sunday. This being so, the Council cannot be accused of losing sight of the religious nature of the foundation of the Fund because in a religious matter where there is room for honest differences of opinion it takes one side more than another. On mere grounds of expediency the Council would be well advised not to move in the matter. We cannot imagine good Christians withholding their subscriptions because other persons, equally good Christians, interpret the ties of religion in a looser manner than themselves. The views of any persons who consider that the money earned by cinematograph shows is infamous, in the manner in which, say, the revenues were infamous of those bishops who for years farmed the brothels of South London, are hardly worth attending to. It will be gathered from this that we sincerely hope that when Mr. SYDNEY HOLLAND has put his views before the General Purposes Committee that body will alter the form of its recommendation. It is our opinion that the Metropolitan Hospital Sunday Fund, without derogating whatever from its high functions as a mainly religious foundation, can well afford to take no action in the matter of Sunday shows.

## Polycythæmia and Plethora.

THE conception of plethora occupied an important place in the pathology of the early and middle parts of the last century, but owing to the experiments of LUDWIG and his pupils upon the effects of artificially increasing the total volume of the blood by transfusion it fell into discredit, and the adjective plethoric applied to the individual of rotund and rubicund appearance was practically all that remained of it. The study of the cytological characters of the blood, more especially by hæmacytometric methods, showed, however, that variations in the individual elements of the blood were common, and on this foundation the modern work upon the various anæmias and upon conditions of leucocytosis is based. It was soon found that the number of red corpuscles might under certain conditions be increased, and to this alteration the names of polycythæmia, polycythæmia rubra, erythrocytosis, and polyglobulia have been variously applied. So early as 1854 it was recognised by J. VOGEL that such a condition might be relative or absolute, depending upon the total number of red corpuscles in relation to the total quantity of the blood. An interesting examination of conditions of polycythæmia and plethora and of their relations to one another is given in a small book[1] recently published by Professor H. SENATOR of Berlin. He differentiates conditions of oligæmia with relative polycythæmia, produced by severe loss of fluid from the body or by the exudation of abnormally great quantities of plasma from the vessels into the lymph spaces, from conditions of plethora serosa—i.e., polyæmia with relative oligocythæmia, and plethora vera—i.e., polyæmia with or without a relative polycythæmia. He goes on to point out that modern teaching in regard to this matter practically dates from the recognition by H. VAQUEZ of the peculiar chronic disease often called after him and characterised by cyanosis, enlargement of the spleen, and polycythæmia, which is more generally known as polycythæmia rubra megalosplenica. Professor SENATOR lays considerable emphasis upon the importance in any condition in which excess of red corpuscles is a feature, of repeated determinations of the red corpuscles, and of collecting the blood for counting from different parts of the body in order to recognise those conditions of polycythæmia which are physiological or which are merely temporary.

A physiological polycythæmia occurs in conditions where considerable loss of fluid takes place without being replaced by drinking, as, for example, after severe muscular exertion and hot-air baths. It may also be observed after heavy meals rich in protein-containing substances, in conditions of convalescence after bleeding and after certain blood diseases, and in newly born infants. Different natural or artificial conditions — living in rarefied air and in high mountain districts, or in the neighbourhood of the sea, and the use of KUHN'S suction-mask—all lead to an increase in the number of red corpuscles. VIERORDT in 1854 described a similar condition in marmots during hibernation. A condition of polycythæmia which must be regarded as pathological occurs as a secondary change in a variety of abnormal states. Among the more important of these may be mentioned a relative polycythæmia occurring after abstraction of fluid from the body by severe vomiting and diarrhœa and by diabetes insipidus, the marked increase in the red corpuscles in conditions of cyanosis resulting from congenital heart disease, emphysema, and that occurring with certain intoxications and infections, especially in poisoning by phosphorus, carbon monoxide, benzine, and certain tar products. It can also occur after administration of tuberculin prepared from the human type of bacillus and in certain cases of chronic tuberculosis, particularly in those in which the spleen is affected. Less commonly it has been seen in association with influenza, trichinosis, malaria, chronic interstitial nephritis, Addison's disease, neurasthenia, and chorea. It is probable here that the excess of red corpuscles is due to diminished oxygen tension in the blood, leading to increased activity of the blood-forming tissues. When all these conditions have been excluded there still exist two forms of primary or idiopathic polycythæmia —viz., the form already mentioned as having been described by VAQUEZ, and a form charactered by high blood pressure and usually by enlargement of the left ventricle, but without splenic enlargement, and known as polycythæmia hypertonica or Geisböck's disease. On the basis of about 50 cases of the former condition at present recorded Professor SENATOR reviews its general clinical and pathological characteristics. The subjective symptoms of which the patients usually complain are vertigo, sensations of blood

[1] Polyzythaemie und Plethora (Polycythæmia and Plethora), von Professor Dr. H. Senator, Geheimer-Medizinrat in Berlin. Berlin: August Hirschwald. Pp. 80. Price M.2.40.

rushing to the head, attacks of headache and sickness like migraine, feelings of fatigue and heaviness of the limbs, dyspnœa, and disturbances of digestion. Among the objective signs is a dark-red appearance of the face, ears, and hands, which is not like ordinary cyanosis. It varies in degree, increasing when the patient is warm. TRUNECEK has drawn attention to a prominence of the supraclavicular fossæ caused by the distension of the blood-vessels, especially the veins. There is often a tendency to hæmorrhage from the nose and gums. The spleen in typical cases is more or less enlarged, but its size may vary in the same patient at different times. Examination of the blood reveals an excess of red corpuscles, the highest values recorded being 13,600,000 and 14,180,000 per cubic millimetre. The specific gravity of the blood may be greater than normal, and values up to 1072 have been noticed. The viscosity of the blood is always greatly increased, even up to four times the normal. Analyses have shown that the total solids of the blood, the iron, fats, and lecithin, are all considerably increased, the blood serum on the other hand being lower in its specific gravity and poorer in solid constituents than the normal. The hæmoglobin is increased usually in about the same proportion as the red corpuscles. The oxygen capacity of the blood is not diminished and may be greatly increased, unlike the condition of polycythæmia occurring in cyanosis from congenital heart disease, in which it is diminished. Recent observations have established that there is an increase in the total quantity of blood, and that therefore the condition is one of true plethora, which, however, does not, as might have been expected, lead to an increase of blood pressure or to cardiac hypertrophy. Professor SENATOR describes the results of some interesting observations upon the respiratory gaseous exchanges in this disease, which are found to be greatly increased. This is attributed to some specific stimulation of the tissue respiration and not to the increase in the red corpuscles and in hæmoglobin. The pathological changes found after death comprise general plethora, enlargement of the spleen, and certain changes in the bone marrow. After reviewing the chief facts in this connexion, Professor SENATOR concludes that the condition is due to a primary disturbance of function on the part of the blood-forming organs.

The other form of primary polycythæmia—viz., Geisböck's disease or polycythæmia hypertonica—has been much less often observed, and only about a dozen undoubted cases are on record. The symptoms are not unlike those of the splenomegalic form, but in about half of the cases apoplectic seizures occur and chronic nephritis and arterio-sclerosis are much more frequently apparent. The patients usually present a typical apoplectic habit of body. Although polycythæmia is obvious and the appearances suggest a true plethora, actual determinations of the total quantity of the blood have not yet been made in this condition. The blood pressure is greatly increased, being often above 200 millimetres of mercury, and values as high as 320 have been observed. Various hypotheses have been put forward in explanation of the pathogenesis of these cases, but none of them are satisfactory. NÄGELI supposed the high pressure was due to increased viscosity of the blood, but it has been shown that a similar increase occurs in the splenomegalic form without rise of blood pressure. MÜNZER attributed the polycythæmia to general arterio-sclerosis, but, as has been pointed out by GEISBÖCK himself, arterio-sclerosis is not a constant accompaniment of this disease. Professor SENATOR suggests that the two varieties of polycythæmia may prove to be related to one another, since cases of polycythæmia without splenic enlargement and with normal blood pressure occur on the one hand, and, on the other hand, splenic enlargement in the splenomegalic form is variable and is not necessarily an early feature of the cases. He suggests a careful search for possible transition cases. It is of interest in this connexion to note that in a paper by Professor R. STAHELIN,[1] published since Professor SENATOR'S book, records are given of seven cases of polycythæmia with increased blood pressure observed during one year, an observation which suggests that the hypertonic form of polycythæmia is more common than the number of cases on record might suggest. The subject is one of practical interest, and offers a field for further observations which may yield valuable information regarding the pathology of the blood-forming organs.

## A Question for Italy.

THE "Third Italy," which celebrates in the year now passing the fiftieth anniversary of the proclamation of its independence, has still much leeway to make up if it would justify, morally and socially, its subversion of the old order in favour of the new. Crime, of a frequency and an atrocity scarcely to be paralleled in its mediæval or pagan predecessors, is as yet a constant quantity in its daily life, maintaining for it what one of its public notabilities has called a sinister priority among its Latin sisters in rapine, brigandage, and homicide itself. No page more sombre in its recent history has, however, been yet disclosed to a painfully impressed world than that which records the assassination of a dama d'onore in waiting on Queen ELENA, the rank and profession of the assassin, the previous history of the latter, and the incidents preparatory to the crime. The "serena e modesta austerità" of the Italian Court, as the leading Roman journal calls it, a moral atmosphere maintained, if not indeed created, by an exemplary King and Queen, throws the lurid tragedy into still stronger relief, and explains the urgency with which, in the Chamber of Deputies, the War Minister was asked to account for the presence in the army of an officer so degraded as the assassin, who, himself a patrician like his victim, had forfeited his right to hold command in a distinguished regiment and enjoy free access to the Royal palace. The Minister could only admit that, in spite of repeated admonishment and even punitive discipline, the Baron VINCENZO PATERNÒ was still tolerated in the service, though a notorious evil liver, whose rôle at his native Palermo, at Rome, Florence, Siena, Lucca—wherever, indeed, he was quartered,—was that of the seducer and the extortioner, seduction and subsequent extortion being his "stock-in-trade" to meet the expenses of a life luxurious and self-indulgent beyond his means.

[1] Berliner Klinische Wochenschrift, Jan. 16th, 1911, p. 101.

With the promise to take stringent measures to prevent such scandals in the service as the continuance of abandoned LOTHARIOS on the official staff, the War Minister seems to have satisfied his interpellants, leaving the well-conducted citizen to moralise on the maxim, "Noblesse oblige," and naturally to infer that crime and violence in so-called "good" society must have their counterpart in the less "good." Imitation, indeed, is ever a potent factor towards degradation of character and breach of the law, and, in proportion to the degenerate individual's retrocession to the animal type, the imitative or mimetic instinct becomes accentuated or reinforced. Herein lies the significance of an awful story.

At this moment the superior Italian press, in full recognition of this instinct, is lamenting the publicity given to the tragedy and anticipating with dismay the recovery of the Baron from the wound inflicted by his attempt at suicide, his removal to prison, and thence to the criminal court, where the revolting details of his career and crime will be served up anew with all the particularity and the repetition familiar to Italian tribunals. In the official organ of the Prime Minister, Signor LUZZATTI, the ablest of Italian publicists and men of letters, GUGLIELMO FERRERO, is utilising the occasion to dwell on the "intellectual bequest of CESARE LOMBROSO," and, while alive to the exaggerations of that strenuous pioneer, is insisting on the scientific value of his main thesis—to wit, that anthropology, particularly in backward nationalities like his own, should have State recognition not only in the establishment of university chairs devoted to the subject but in the opportune surveillance of tender youth, in anthropometric examination reinforced by medical inquiry into family history, and in the adjustment of elementary education in harmony with their findings. From Palermo comes testimony as to the type to which the assassin and would-be suicide Baron PATERNÒ belonged—one in which the animal instincts were abnormally and precociously strong,—the unbridled gratification of these inducing a physical and moral deterioration till the adult was already a victim to neurasthenia and morally as well as physically septic. Gambling for high stakes; plunging into the vortex of pleasure uncontrolled by any feeling of professional responsibility, or, indeed, of self-respect; hopelessly enmeshed in the toils of the money-lenders; and sticking at no device for raising funds; paying court to married ladies of his own class, and if possible compromising them till he could extort hush-money to save them from the scandal he had contrived,—such were the methods, such the career, of this young cavalry officer till, on his latest victim, the amiable, accomplished, universally beloved, if weak, Contessa TRIGONA, refusing him a sum which would have ruined her (already sorely reduced in means by his exactions), he decoyed her to an obscure hotel in Rome, and there drove a stiletto into her throat from which she died instantaneously, while the revolver which he discharged below his ear seems to have taken but partial effect. And all this transacted in an aristocratic *entourage*, nay, involving one of the *personnel* of the Court, and in the year when Italy is proclaiming to the world the blessings of the new departure she took 50 years ago! Verily, the cynic may be excused for asserting that sin and crime are a constant quantity, in spite of "progress" and "civilisation" and "culture," but it is the duty of medicine to reinforce the educational efforts necessary to prove the fallacy of the creed that "man was made to mourn" for ever.

"Ne quid nimis."

## THE ROYAL SOCIETY OF MEDICINE: THE SOCIETY'S NEW HOUSE.

WE publish this week a brief account of the new house which is now being built for the Royal Society of Medicine on a very appropriate and convenient site where Wimpole-street runs down into Henrietta-street, Cavendish-square. The exigencies of our space have compelled us to reduce greatly the reproductions of the plans, but a key to the size of the various departments is furnished by the noble dimensions of the library. The library extends the whole length of the building, being 110 ft. long, and appears in Fig. 5 on p. 759 as 2½ in. long only. The Council and officers of the society are, in our opinion, to be warmly congratulated on their choice of plans and on the design of their architect, Mr. John Belcher, R.A., which is well shown in the special plate. It now remains for the medical profession to take its part in supporting an institution which is playing, and is destined to play more fully, the rôle of an academy of medicine in this country. The financial position of the society is perfectly clear, and is one that justifies the belief of all who have looked into the matter that great prosperity lies ahead. To some extent, however, that prosperity is bound up in the society's house—it is important that the house should go up quickly and that there should be left behind no legacy of debt. When the society possesses its noble headquarters the membership is bound to increase, but in the meantime the building has to be paid for. The lesson seems to us to be that the intending member should not wait till the house is erected before joining the society, and that the intending donor should take his cheque-book and sit down quickly and write the figure suggested in the parable, or more.

## THE END OF THE CHOLERA EPIDEMIC AT MADEIRA.

NEARLY three weeks having elapsed since any case of cholera was reported, Madeira has been declared officially free from the disease. The first cases are believed to have occurred about Oct. 14th, and the nature of the disease was officially recognised only on Nov. 26th. The official returns show that the disease attacked 1769 persons and that the deaths were 556. An analysis of cases which, it is understood, will be issued later by Dr. Carlos França will throw much light on the merits of different modes of treatment, and perhaps also on the manner in which the disease spread amongst the people, but meanwhile the following facts are available and are of general interest. The onset was acute in 75 per cent. of the cases; insidious and gradual in 25 per cent. The duration of the disease was from three to ten days. Cramps during the first 24 hours were present in 95 per cent. The vibrio was found in hardly 10 per cent. in the vomit. A very small percentage lapsed into a quasi-typhoid condition subsequent to the cholera symptoms, a condition which lasted some 10 days. Of five pregnant women four aborted; 10 per cent. of those attacked were known to be habitual alcoholics. Amongst about 350 persons who having been in contact with cholera patients were

placed in isolation, many were observed to carry the bacillus for more than three weeks without any cholera symptoms, but out of 71 nurses and attendants at the lazarette hospital not one contracted the disease or showed the presence of the bacillus in the excreta. Amongst the complications only two or three died from uræmic coma, but many suffered from protracted anæmia. Twelve cases of urticaria were observed, and there were nine cases of intestinal hæmorrhage. There were ophthalmic symptoms, mainly conjunctivitis, in more than 30 instances. The epidemic spent itself amongst the most careless, the dirtiest, and the least instructed of the people; and the general mortality would have been greatly mitigated if the cases had been notified earlier, and if some effective treatment had been possible before collapse set in and before it was attempted to remove patients so gravely ill to a distant hospital. "But all is now over," writes our correspondent on the island. "Holidays are decreed, and Funchal is *en fête*. It becomes us, nevertheless, to press upon the authorities the urgent need of works, both of amelioration and development. During the last few weeks the barometer, standing at a high level, has hardly varied 1-10th of an inch. The temperature has been steady at about 65° F., and the island has been bathed in a dry, gentle, descending current of air. The registered sunshine has been about 10½ hours per day. The hygrometer has shown 8°–10° of difference (dry and wet) at the temperature of 65° F. In a more concrete way the climate is illustrated by the profusion of flowers, the abundance of strawberries and English summer vegetables at this season. Madeira is hardly more than three days distant from England, and the policy of the Government, which in Republican form is working smoothly, should be to make their priceless possession generally available."

## PAINFUL DOUBLE TALIPES VALGUS OF TUBERCULOUS ORIGIN.

IT has been known for a good many years that under the term "rheumatism" there lies concealed a number of different causal factors united only in the common clinical features of pain, chronicity, and the absence of marked physical signs in the parts affected. Various micro-organisms have been described and figured by different workers as related to rheumatism; the gonococcus has been proved responsible for some varieties; "painful heel," thanks to skiagraphy, has been successfully operated for; and results have been published showing the success of various vaccines and serums in ameliorating or curing certain conditions. The fact, however, that the tubercle bacillus may be the underlying cause in certain of these rheumatic conditions, more especially of the feet, has not been sufficiently recognised in this country, although so long ago as 1905 Molinar, working under Poncet, published a thesis on the subject.[1] No apology, therefore, is necessary for drawing the attention of the profession to a case of painful double flat foot of tuberculous origin described by Professor Poncet in the *Gazette des Hôpitaux* of Dec. 31st, 1910. The patient was a sempstress, 30 years of age, who came complaining of pains in the calves of the legs and soles of the feet. As a child she had been rather delicate. At the age of six she had eye trouble lasting from 16 to 24 months, and leaving a permanent opacity on the right cornea. Menstruation started at the age of 13, and was regular. In 1901 she had a normal confinement, and it was from that time that she dated the frequent rheumatic pains and persistent slight cough from which she had suffered every subsequent winter. In 1906, owing to the persistence of this cough and a gradually increasing loss of weight, she was medically examined and found to have signs of pulmonary tuberculosis in both apices. For this she was admitted to a sanatorium, where she remained six months, being discharged much improved but not cured. In February, 1907, during a busy season for her, she first noticed pain in the right foot. The pain grew gradually during the course of the day, was made worse by standing and walking, and was situated in the sole of the foot in the region of the astragalo-scaphoid articulation, and underneath the external malleolus. Rest in bed at night caused it to disappear, though an indefinite tenderness persisted. Gradually, however, during the year pain became more constant, rest had less effect on it, the left foot also became involved, and eventually in November she had to give up work. At that time, when examined by Professor Poncet, there was no apparent lesion, swelling and discolouration were absent, and the joints moved freely. There was, however, some wasting of the calf muscles. When seen again, however, four months later, on account of the severity of the pain, she had in the interval acquired marked valgus, most pronounced in the right foot. The soles of the boots were worn away on the inner side, and with the boots off there was seen to be a marked sinking of the plantar arch. The internal malleolus and the scaphoid projected abnormally, the heel was inclined inwards, and the fore part of the foot made with the hind part an angle open outwards. There was marked loss in the power of the peroneus longus, and a finger could be inserted between the ground and the head of the first metatarsal. The left foot was not so markedly involved, but in both feet the plantar arch was obliterated. When fitted with specially designed cork boots she was able in a few months to walk a little without much pain. Walking in slippers, however, was impossible. A course of waters at Aix-les-Bains in 1909 seemed to improve her condition, but in the spring of 1910 the pains had spread to other joints, so that she was unable to move or do any work. The shoulders, knees, and articulations of the fingers became involved in succession, and the clamminess characteristic of joint affections was present. The pains, however, were not constant, but moved from one articulation to another. In August, 1910, she returned to Aix for another "cure," and at the time of writing is so much better that she is able for a short time to discard the orthopædic boots for ordinary footwear. The case as described is one of ordinary rheumatism. There is apparently no suspicion of gonorrhœal taint, and there is no leucorrhœal or other vaginal discharge; and Professor Poncet does not hesitate to ascribe a tuberculous origin to the affections of the feet.

## THE SEVENTEENTH INTERNATIONAL CONGRESS OF MEDICINE.

THE Seventeenth International Congress of Medicine will meet in London in the summer of 1913, as perhaps our readers hardly need to be reminded. The exact date is to be fixed by the International Permanent Committee, which will assemble in London on April 21st and 22nd next, under the presidency of Dr. F. W. Pavy. At the same meeting the list of sections of the Congress will be constituted. Any wishes or propositions concerning the arrangement of this list may be sent, up to April 1st, to the honorary general secretary of the Permanent Committee, Professor H. Burger, Vondelstraat 1, Amsterdam, or to the Bureau of the committee, Hugo de Grootstraat 10, The Hague, Holland. The committee will be glad to receive, before the same date and at the same addresses, any information or propositions concerning the organisation of the Congress which interested parties may desire to forward. Our last references to the arrangements for the Congress will be found in THE LANCET of Oct. 22nd (p. 1234) and Nov. 5th, 1910 (p. 1368), and some particulars of the International Permanent Committee will be found in THE LANCET of April 16th, 1910, p. 1091.

Dr. W. P. Herringham, of 40, Wimpole-street, London, W., is the secretary of the 1913 Congress.

## QUARANTINE FOR DIPHTHERIA CARRIERS.

THE energetic measures taken in Chicago to place antitoxin at the disposal of the entire population have already been described.[1] Though last year there was a recrudescence of this disease, it is encouraging to see that the death-rate has on the whole been enormously reduced. Nevertheless, this has not prevented a great increase in the number and the severity of the precautions taken. The statistics of the last five decades have just been published by the Chicago health authorities, and these show that from 1860 to 1869 the average annual death-rate from diphtheria amounted to 159 per 100,000 of the population. From 1870 to 1879 it was 112, from 1880 to 1889 it was 174, from 1890 to 1899 it was 93, and from 1900 to 1909 there were only 22 deaths per annum due to diphtheria per 100,000 of the population. Undoubtedly this wonderful result is in the main due to the use of antitoxin, and even more lives would have been saved if in all instances the proper measures had been taken as soon as the diagnosis of the disease had been established. With the use of antitoxin must also be associated measures of isolation and disinfection, and these later precautions have now to be applied not only to patients but also to disease carriers. This latter measure is especially difficult to enforce. But the Chicago Health Department has boldly seized the bull by the horns. The throats of apparently healthy school children have been examined. If a single case of diphtheria occurs in a school cultures are made from samples taken from all the throats of the children attending that school. When it is thus demonstrated that, though a child is apparently in good health, it is a carrier of diphtheria bacilli, the child is at once isolated and kept in quarantine till there are no more pathogenic bacteria in its throat. Outside the door of the room where the child is thus confined a card is suspended, bearing the following inscription:—

CARRIER OF DIPHTHERIA
HERE.
KEEP OUT.

Then in smaller type there is the following explanation:—

A diphtheria "carrier" may not be sick, but has diphtheria germs in the throat and can spread diphtheria. Such persons will be required to stay in the house until the throats are free from germs. Cultures will be taken to determine this. Other persons in the house can go in and out. Neighbours and friends must stay out. Milkmen must take the usual precautions. These rules must be obeyed until this warning card is taken down by the Department of Health.

Naturally not a few parents have rebelled against the severity of such enactments, and in some instances have been supported by local medical practitioners. The latter called in had looked at the child's throat in the usual way, and had failed to detect that there was anything suspicious. But these practitioners are now realising that such measures are only taken by the authorities after bacteriological analyses. This service entails a very great increase of work. At one moment the Chicago Municipal Laboratory received more than 1000 throat cultures to examine per day. In two schoolrooms, where there had been cases of diphtheria, no less than 25 per cent. of the children, though apparently in good health, were found to be carriers of the diphtheria bacilli. When such a crowd of children had to be put in quarantine it will easily be imagined that these novel and stringent measures caused no small commotion. This new service was first instituted last December, and for the week ending Dec. 16th, 1910, there were 239 new cases of diphtheria notified and 258 carriers. But for the next week there were not more than 150 carriers, though the new cases were nearly as numerous—namely, 224. A week later—that is, the last week of last year—the number of carriers had fallen to 53, and the cases of actual disease were reduced to 146. Only five carriers had been discovered the first week and seven the second week of the new year, so that this source of danger has been largely overcome, and the disease itself seems to be slowly dying out.

## GONORRHŒAL INFLAMMATION OF THE VAS DEFERENS SIMULATING APPENDICITIS.

IN the *Bulletin de la Société de l'Internat des Hôpitaux de Paris* for January M. René le Fur has reported seven cases in which gonorrhœal inflammation of the vas deferens simulated appendicitis. Statistics have been published to show that in about 40 per cent. of cases of gonorrhœal epididymitis the vas deferens, prostate, and vesiculæ seminales are involved. M. le Fur goes much farther than this, and states that, having systematically examined these parts per rectum in all cases of gonorrhœa, acute or chronic, he has always found them involved in cases of epididymitis. The cases of inflammation of the vas simulating appendicitis may be divided into two classes—those which are accompanied by epididymitis and those which are not. The former cases may clinically take several forms—acute, subacute, or chronic, just as may appendicitis. Cases of very acute epididymitis, with severe pain in the abdomen and right or left iliac fossa, vomiting, obstinate constipation, tympanites, and a temperature of 104° or 105° F., due to an intense peritoneal reaction and exactly simulating the symptoms of acute appendicitis, are well known. These symptoms are due to concomitant inflammation of the vas and vesicula seminalis which has involved the cellular tissue and even the peritoneum covering the pelvic part of the vas and the vesicula seminalis. The following is an example of inflammation of the vas simulating appendicitis. A man, aged 25 years, had slight epididymitis about the fifteenth day of a first attack of gonorrhœa. In the fourth week on returning from a railway journey he was seized with violent pains in the right side of the abdomen, tympanites, vomiting, and a temperature of 105° F. There was absolute constipation and flatus was not passed. He showed the pinched peritoneal face. He and his famlly were very uneasy, and thought he was suffering from appendicitis. M. le Fur reassured them, though he was himself uneasy, and prescribed opium and the application of ice to the abdomen, which relieved the pain. But on the following day the vomiting and the fever persisted, there was some delirium, the tongue was dry and furred, the pulse was rapid and weak, and the tympanites had increased. M. le Fur then diagnosed appendicitis and called in Professor Berger, who confirmed the diagnosis of appendicitis, but advised against operation, and recommended that the treatment be continued. For two days the condition of the patient was serious. There were a frequent and imperious desire to micturate, and a feeling of weight in the lower abdomen and fundament. On the fifth day the urethral discharge, which had disappeared completely, reappeared in an abundant form. Rectal examination showed that the right vesicula seminalis was much enlarged and painful; the vas deferens could be followed along the pelvic wall as an elongated painful swelling. On pressure on these organs and on the prostate pus exuded from the urethra. Further, there was in the pouch of Douglas a median swelling of the size of a Tangerine orange, which was painful and soft. The urethral injections were resumed, suppositories of thigénol were inserted, and the bladder was washed out with a 1 in 4000 solution of permanganate of potassium. Rapid improvement took place. The diagnosis

was altered from appendicitis to spermatocystitis and inflammation in and about the vas deferens with intense peritoneal reaction. Under massage of the vesicula seminalis and vas deferens, warm injections, and suppositories the swollen vas diminished, but complete absorption of the swelling as well as of the tumour in the pouch of Douglas occupied a long time.

## THE SANITARY OFFICERS (OUTSIDE LONDON) ORDER, 1910.

A MEETING of medical officers of health, representing 30 sanitary districts in the Administrative County of Devon, was recently held for the purpose of discussing with the county medical officer the extra duties imposed on them by recent legislation in public health matters. Among the subjects discussed was the Sanitary Officers (Outside London) Order, 1910, upon which a resolution was passed requesting from the various authorities "an increase of salary as suggested by the Local Government Board, on account of the many extra duties thrown on medical officers of health" by recent Orders and enactments. In a leading article in THE LANCET of Jan. 21st, p. 175, we discussed this Order of the Local Government Board and the memorandum which accompanied it, and we drew attention to the expressed opinion of the Board that "it is not sufficient merely that a medical man is found who is prepared to accept the salary offered; it is more important that the salary should be such that it will be worth the while of a capable man to accept it and to give a sufficient amount of time to his duties." We also stated that the particular risk which the medical profession runs at the present moment is that insufficient salaries should be offered and accepted for the discharge of amalgamated duties. It is in part-time appointments especially that the imposition of extra duties is a sufficient justification for the request for an increase in salary, owing to the loss that is incurred from lessened opportunities for other work. We trust that the legitimate requests of those part-time officers of the sanitary districts in Devon for increase of salary will be met by the various authorities concerned with understanding and compliance.

## THE PREVALENCE OF TRACHOMA IN FINLAND.

FINLAND has long been the home of trachoma, which under the name of catarrhal ophthalmia was stated in 1832 by Sanmark to be the cause of illness in more than half the patients in the hospital for infectious diseases in Vasa. Improved hygiene has now bettered matters considerably, but the result of an *enquête* by the Finnish Government in 1908 shows that the disease and its sequelæ, such as entropion and pannus, still are a national scourge. This material has been recently analysed by Grönholm and Kuhlefelt,[1] who estimate the present incidence of the disease at the high figure of 130,000, or 4·3 per cent. of the total population. In 1908 5273 patients were treated for this disease, and of the 83,052 Finnish imigrants in the years 1903–08 3511 were affected. In schools, factories, prisons, and other public institutions 1293 patients were discovered in a total of 26,000 persons examined. The disease was found less frequently in men than in women, 3·3 per cent. of the former and 5·2 per cent. of the latter being affected. The disease was most frequent in early adult life, but it was common at all ages. Of the labouring communities, the peasants on the land suffered more frequently than mechanics and factory hands, while among the upper classes the disease was relatively rare. The population of Finland consists of a Swedish-speaking and a Finnish-speaking element; the disease was found to be almost exclusively confined to the latter element, probably owing to its insanitary habits. Several charts illustrate the prevalence of the disease in various districts, and the similarity, on the whole, in the geographical distribution of trachoma and tuberculosis. The astonishing observation is made that only 4·1 per cent. of the total number of patients sought medical aid in 1908. Many factors contribute to this apathy on the part of the patients. The disease may exist for years as granular conjunctivitis without troubling the patient to any great extent. The condition may even heal spontaneously without being recognised. Again, in the later stages of granular conjunctivitis scar formation, entropion, and trichiasis may attract but slight attention. Many patients also who realise that their blindness is incurable find little comfort in medical attendance. Unfortunately, even in the active stage of the disease, when there are lacrymation, œdema, defective vision, and pain, medical aid is not invariably sought, though more frequently in the towns than in the country. Thus in Helsingfors 25·1 per cent. of the patients consulted medical men in 1908, while in a country district the contemporary percentage was 1·9! This deplorable neglect of the disease naturally leads the writers to the vexed question of compulsory notification, and the treatment of patients at the cost of the State. Their proposals are based on the regulations in force in Hungary and Germany, where the disease has been materially reduced by compulsory notification, by medical inspection of school children and other groups of the community, and by the establishment of polyclinics and labour colonies for the patients. The appointment of medical officers specially trained for the work in the worst districts is also desirable. These regulations may be costly enough, but the annual loss to the nation from total and partial blindness warrants considerable expense in stamping out the disease. About 1000 (or one-third) of all cases of blindness in Finland are due to trachoma. Add to this figure the number of workers whose productive powers are more or less reduced by partial blindness, and the nation's pecuniary liability (if insurance against sickness existed on German lines) would, indeed, be heavy.

## PLAGUE IN GERMAN EAST AFRICA.

IN February last there was published in the *Archiv für Schiffs und Tropen-Hygiene* an account of a plague epidemic, mainly in rats, in the vicinity of Lindi. The date is not mentioned, but seems to have been in August and September, 1910. The infection was virulent—a native baby died after only two hours' illness, but only three cases of human plague occurred, and this is ascribed to the early recognition of disease in rats and to strenuous measures at once taken for their destruction. Of 520 rats caught in the first month 5 per cent. were infected; later in the epidemic the proportion increased to 14 per cent. The writer of the report, Dr. Manteufel, agrees with the opinion of the Bombay Plague Commission, that the epidemic must be very widespread among rats before it begins seriously to attack men. He found that mus decumanus was more attacked than mus rattus (8 per cent.: 1½ per per cent.). Few mice were caught, but they were heavily infected. In Hong-Kong it may be said that mus rattus is two or three times as often infected as mus decumanus. Dr. Manteufel considers that his experiences at Lindi prove the spread of plague by fleas because the guinea-pigs, exposed as flea-traps, contracted plague and died, and pulex cheopis (three males, one female) were found on one of those that died; they had all buboes in the neck, none in the mesenteric glands. Mesenteric buboes occur in animals infected by feeding on plague material, and no mesenteric buboes were found in rats that died during this epidemic. Rats that were healthy when caught carried few

fleas. Plague-infected rats had many fleas, two-thirds of those enumerated being carrier fleas, pulex cheopis. One rat covered with fleas had ulcers on the skin of the abdomen in which flea larvæ were found. If there were plague buboes in rats bipolar-staining bacilli were also found invariably in the spleen, but these might be found in the spleen though there were no buboes. He concludes that plague can be best prevented if the rats are carefully watched and their having become infected be discovered before the epidemic is widely generalised among them. Then they are to be assiduously diminished, and the danger will have passed away before the general public has come to a knowledge of its danger. On April 2nd, 1910, we noted an epidemic of plague which had occurred at Dar-es-Salam in German East Africa.

## THE INTERNATIONAL CONGRESS ON TUBERCULOSIS AT ROME.

THE arrangements for this country for the forthcoming International Congress on Tuberculosis, which will meet in Rome from Sept. 24th to 30th, 1911, have been placed in the hands of the National Association for the Prevention of Consumption and other Forms of Tuberculosis, 20, Hanover-square, London, W., at the request of the Italian authorities. An executive committee has been formed for the purpose of arousing interest in the congress in this country, and for collecting information, papers, &c., and inducing local authorities to send delegates to the congress. The following form the committee: Sir Shirley Murphy, Professor William Osler, Professor G. Sims Woodhead, Dr. Arthur Newsholme, Dr. Theodore Williams, Dr. T. D. Acland, Dr. Hector Mackenzie, Dr. E. W. Hope, Dr. Nathan Raw, Dr. R. W. Philip, and Dr. J. J. Perkins, who will act as honorary secretary. A representative national committee has also been formed. Anyone who is interested in the congress should apply to the honorary secretary of the National Association for the Prevention of Consumption, 20, Hanover-square, W., for particulars, and any intending contributors should send in their papers to the same address.

A CONFERENCE was held on Tuesday afternoon last, March 14th, at the Local Government Board, over which Dr. A. Newsholme, principal medical officer to the Board, presided, the subject of consideration being what steps should be taken to arrest the present epidemic of measles in London. The majority of the metropolitan medical officers of health were present in addition to Dr. R. H. Crowley, representing the Board of Education, Dr. Theodore Thomson, assistant medical officer of the Local Government Board, Sir Shirley Murphy, and Dr. J. Kerr. Mr. Burns, at whose instigation the conference was held, took part in the proceedings.

THE King has sanctioned the promotion of the following gentlemen from Honorary Associates to Knights of Grace of the Order of the Hospital of St. John of Jerusalem in England: Dr. P. Frank, Dr. F. A. Brooks, and Mr. Edwin Lee.

ROYAL SUSSEX COUNTY HOSPITAL, BRIGHTON.—The committee of management of the Sussex County Hospital at Brighton on March 8th received an official letter from the Home Office stating that His Majesty the King had been graciously pleased to command that the hospital shall henceforth be known as the Royal Sussex County Hospital. The institution was inaugurated in 1828, and has had each reigning monarch as its patron. The hospital has been extended from time to time, and its present extent can be gathered from the figures for 1909, when the in-patients numbered 2359 and the out-patients 10,046. The cost of maintenance is in round figures £15,000 per annum.

# AN EGYPTIAN HOLY MAN.

BY C. G. SELIGMANN, M.D. LOND., M.R.C.P. LOND.

THE title of this note has been chosen because it deals—though doubtless incompletely—with the outward manifestations of the spiritual development of Mohammed Moussa, an Egyptian *fellah*, which led to this man being recognised as especially holy (*maburak*) by his companions. My opportunity of studying Mohammed Moussa occurred while a guest at Professor Petrie's camp at Qurneh in January, 1909, and I desire to take this opportunity of thanking him and his assistant, Mr. Ernest Mackay, for much kindness and assistance, while I am also greatly indebted to Mr. Brian Hatton for the drawing of a *zikr* which illustrates this paper.

Mohammed Moussa is a native of Qift, and is one of the men who for some years have worked each winter for Professor Petrie. He is recognised by his fellow workmen as distinctly holy; in fact, those to whom I talked concerning him admitted that if he persevered in holiness he might after his death be honoured as a holy man. Mohammed Moussa is rigorous in the observance of the prayers and customs which are enjoined on all Muslim, but these virtues are so general in his fellows that they can have had little part in producing the belief in his exalted spiritual status, which at the time of my visit was in fact due to the ease with which he passed into a condition of ecstasy.

Mohammed Moussa, whose photograph, taken by Mr. Mackay, is reproduced in Fig. 1, is a middle-aged man of the usual stout build and moderate stature of the Egyptian *fellah*. He is a good and steady worker, and presents no tricks of manner or behaviour to differentiate him from his fellow workers. He had not been subject to any form of fit or seizure when a child, though even as a young boy he was very religious. His first ecstasy appears to have occurred during adolescence—certainly after puberty, and probably between 17 and 20 years of age.

FIG. 1.

Mohammed Moussa.

The occasion of my becoming aware of Moussa's attacks of ecstasy was a *zikr* held by his fellow workmen in thanks for the recovery from sickness of one of their number, Mohammed Osman. Osman had during his sickness vowed that on his recovery he would hold a *zikr* and kill a sheep; the sacrifice of the sheep he postponed until his return to Qift, but after the *zikr* sweetmeats and *karob* beans which he provided were distributed among all present. *Zikr* usually, but not invariably, takes place after sundown. They may be held on any day, but my Qift informants considered Fridays, Mondays, and Thursdays the most appropriate days. Though especially in the nature of a thanksgiving they are popularly regarded as meritorious, and their performance is, in fact, a religious act to all who take part in them. The

literal meaning of *zikr* is "remembrance" or "bringing to mind" (of God's glories), and Lane has recorded their occurrence among the Cairenes at a number of public and private ceremonies. They may be held in honour of a dead man, and there seems to be a popular and entirely unorthodox belief that his soul may thereby be helped in Paradise.

The *zikr* during which I first saw Mohammed Moussa pass into ecstasy began by a number of men standing in two parallel rows facing each other, one row being longer than the other, the latter consisting largely of small boys, and as they wearied of the dance this row ceased to exist. Between the two rows at the far end was one man Ali Hamid, assisted by Mahmud Ghalad, who is a *sayid*—i.e., a descendant of the Prophet. These men intoned certain songs said to be very old, which Mr. G. D. Hornblower (to whom I am indebted for much information relating to the *zikr* and kindred subjects) informs me were probably *medh*, i.e., praises of the Prophet, the men forming the rows dancing vigorously between the songs. Their rhythmic bowing and swaying motions were accompanied by a loud throaty inspiration or by the ejaculation of one of the names or attributes of Allah. The commonest ejaculations were *Allahu qaim*, "God is the established"; *Allahu qadir*, "God is omnipotent"; *Allahu daim*, "God is everlasting"; and *Allah haq*, "God is just." The words were by no means clearly articulated—indeed, the last expression was shortened till all that could be heard was a deep expiratory grunt. Each expression of praise was repeated continuously during the whole of one figure, regulating or being regulated by the rhythm of the movement it accompanied. The movements, which usually started with a moderate flexion of the neck and upper part of the body, became wider and more vigorous as each figure proceeded; sometimes a loud thudding noise was produced by raising the heels, the row bringing down the feet simultaneously. In one figure the feet were planted thus \/ and not moved, but the body rotated at the hips to the greatest possible extent each way so that the faces of the dancers turned through nearly 120°. In another figure the left foot was advanced with each flexion of the body and the weight of the body supported upon it. Perhaps each "figure" lasted five minutes, the intervals of rest being half as long.

FIG. 2.

The beginning of a *zikr*.

After about one and a half hours the dance had dwindled to six men, of whom Mohammed Moussa was one. He had joined the dance late and had probably not been dancing more than 20 minutes before he passed into ecstasy. At the end of a figure he several times recited the confession of faith, *La ilaha ill'Allah Mohammedu rasul Allah*, in a harsh guttural voice. This was evidently considered as the beginning of ecstasy, for his right-hand neighbour, Nasr-ud-din, firmly linked his arm in his, but the first physical signs I noted were general rigidity of the body, accompanied with tremors from the legs upwards, the neck was strongly extended, the eyes shut, and at first the lips moved. Then Mohammed Moussa jumped up and down on the tips of his toes several times, after which with head thrown back he struggled violently, but was held by his neighbour while another man patted his breast and back as though to soothe him. His struggles became more violent, his head was thrown back, his teeth tightly clenched, each inspiration was deep and laboured, he frothed at the mouth and his saliva was blown about during expiration. At first supported upright by his companions he was soon lowered to the ground, where he was sustained in a sitting posture, his pulse at this time being 96. His lips moved, and I was informed that he was now having a vision; his head was slightly bent forward, so that he looked on the ground; his arms were rigidly extended at his sides and could only be flexed slowly. The onlookers carefully bent his left arm into a position of maximum flexion, so that the hand touched the shoulder; the rigidity of the right arm was similarly overcome and the arm and hand placed in the same position. All the men sat down and began chatting; Moussa sat still, occasionally swaying his body and muttering, while the people around him now and then patted his chest and back. This probably lasted about three minutes until Mahmud Ghalab whispered something in Moussa's ear. He started and appeared to come to himself instantly, looking round as if puzzled, while his neighbours laughed; then draping a cloth over his head he recited what I was told were his trance experiences, every now and then kissing a cloth in which he had wrapped his hand. After kissing it he passed the cloth and hand across his forehead, this being a form of thanksgiving. During his recital the crowd filled his pauses with a chorus of the confession of faith in a low impressive murmur. When this was over Moussa took his head in both hands and twisted it round as far as possible in each direction. He was left sitting down and appeared perfectly rational, for when one of the party said "Good night" he answered correctly in a perfectly normal manner. Sweetmeats and *karob* beans were then handed to all.

In answer to my question I was told that Moussa had never bitten his tongue during ecstasy, in which state he visits Paradise (*Genna*), where he sees the saints and prophets and many green birds. His visions do not vary. On his return to the common state of existence he is neither giddy nor nauseated—indeed, as the whole matter is directly from Allah he could suffer no hurt. The flexion movements and the whispering in Moussa's ear are avowedly to restore consciousness.

On another occasion when a *zikr* was held Moussa thrice failed to keep time and twice laughed loudly and appeared to be on the point of ecstasy, but each time after a slight struggle, during which his neighbour Nasr-ud-din took hold of his arm, he again took up the rhythm of the dance. The fourth time that this occurred Moussa struggled violently with Nasr-ud-din, attempting to rush away into the darkness, and succeeding in dragging his friend a yard or two from the line before he became rigid and collapsed in his arms. Moussa was brought round in the manner already related, but on this occasion he did not relate his experiences while in ecstasy.

It is, I think, obvious that Moussa's ecstasy is an example of the condition known as hysteria major or hystero-epilepsy. I do not now propose to discuss the diagnosis and will only refer to the rigidity of the arms to say that I took part in bending one of Moussa's arms and was able to

convince myself that the rigidity of the muscles was only overcome slowly under influence of firm pressure continued for some little time. At the time of my visit Moussa had not during ecstasy or at any other time performed, or attempted to perform, any unusual acts such as are by repute commonly performed by Egyptian dervishes during ecstasy. Perhaps the commonest of these acts is to eat living snakes and to handle scorpions, and Moussa's comrades had no doubt as to his capacity should he wish to do either. This was because he was recognised to be under the protection of Sheikh Rifa'i, to whose devotees snake-bite is harmless, while scorpions, it is alleged, do not bite them.[1]

The next manifestation of Moussa's holiness is described by Mr. Mackay as follows, my own interpolations being placed between brackets. "On May 7th, 1909, I was informed by my head man that two strangers from the Fayum were giving in the village of Mitrahinch performances of various conjuring tricks, together with the handling and biting of red-hot bars. The two men were accordingly invited by myself to come in the evening and show what they could do, a large fire of wood and several irons for heating being provided outside the courtyard of the house. When the work for the day had finished, and after the workmen had had their evening meal [i.e., in the late twilight], the two men from the Fayum made their appearance provided each with a drum. Our men from Qift quickly formed a circle by sitting around the fire, and the two bars were placed in the centre of the fire to get hot. The proceedings opened by a *zikr* being performed by the two strangers sitting down, and in the intervals of this the elder of the two repeatedly told the onlookers to repeat the Fatiha. When about a quarter of an hour had elapsed with this, one of the men, the elder again, walked to the fire and took out one of the irons which was glowing hot [at the other end], walking around the ring and showing it to everybody. He then stood close to the fire and said a few prayers calling upon Sheikh Hussein [Egypt's principal saint, brother of Hassan and of Ali and grandson of the Prophet]. By the time these were finished the iron had become a dull red. It was then repeatedly and carefully licked by the man, who, I noticed, had his tongue well moistened and who drew it in after contact with the iron. The bar was finally held between the teeth of the man for a few seconds. A clumsy and long conjuring trick followed this. I then requested one of my men to ask the performer to lick the other iron in the fire with a dry tongue, and he at once advanced to the fire and took out the remaining bar, which, as it had been longer in the fire, must have been hotter than the first. He then was about to go through his previous performance, when with a loud cry Mohammed Moussa, who was one of the onlookers, rushed into the ring, and, snatching the iron from the man, held it [for more than ten seconds] at both ends and walked around the circle crying, 'Allah! Allah! Allah!'[2] He did this several times, and finally stood in the centre of the ring, close to the fire, holding the iron between his lips for at least ten seconds or more, swaying about as he did so. He then dropped [threw down] the iron and went into the usual *zikr* fit [i.e., a hystero-epileptic attack, *cf. supra*]. Directly the iron was dropped [thrown down] he went into a fit, and his attitude in putting [dropping] it down was as if he had grown tired of it. No word was spoken by any of the men while he was using it to my knowledge. He did not apparently try and cover any special distance, but just walked in the circle formed by our men. At this juncture I had the irons removed, fearing serious consequences to Mohammed Moussa if he should get hold of them again. After he had recovered from this fit, which lasted two or three minutes, in which he was not attended, he cried out again, 'Allah!' and rushed to the fire, and, seeing the irons were not there, demanded them. On being soothed by one of our men he stooped over the fire and threw some of the red hot embers over himself with his bare hands, burning his garments in one or two places. The irons were then again demanded, and one or two of his friends tried in vain to make him sit down; he dragged them around the ring together with a third man who got up to give assistance. Someone then suggested that a *zikr* be started to quiet the man, and this was done, a row of men being quickly formed and Mohammed Moussa placed in their midst. As soon as the performance was started he quieted down and joined in, shortly after retiring with a few of his friends to smoke a cigarette. I then went up and found him quite rational and self-possessed and examined his hands with the aid of a lantern, but could find no trace of burns or any injury. The next day a further examination was made by me, but no signs whatever of burns or even a redness could be seen either on his hands or lips. Also he worked all day as usual with the pick, and though I closely watched him he showed no signs of any tenderness in his palms. The men all tell me that this was the first time he had ever performed this feat to their knowledge, and they were accordingly all astonished. Mohammed Moussa informed me, when I asked him as to what made him get up as he did that he saw the man from the Fayum was a fraud, and something told him that he could perform the feat properly himself. He also seemed rather surprised at my wanting to look at his hands, and said that when he was under the protection of Sheikh Rifa'i no harm could possibly come to him. I may mention before closing that the juggler from the Fayum told me, to cover his discomfiture, that Sheikh Rifa'i was a much more powerful saint than his own—namely, Sheikh abu Salaam, and to this he ascribed the success of Mohammed Moussa." Concerning Mohammed Moussa's condition when he picked up the iron Mr. Mackay writes that he "was not to my mind unconscious when he took up the iron; he seemed in the condition you observed at Qurneh (just before a fit); I think it would be safe to say he was semi-conscious." Further, on examining Moussa's hands by lamplight Mr. Mackay found that he remembered what he had done.

The events which took place before May 7th, 1909, present the ordinary features of ecstasy, and accord with what we know of the physiology and pathology of the nervous system and are certainly not opposed to the accepted teachings of the biological sciences. The reverse applies to the manifestation of special power or holiness witnessed by Mr. Mackay on May 7th, 1909, and although I am not convinced that Mohammed Moussa was at the time able to handle red-hot iron without being burnt, I have reproduced Mr. Mackay's written account of Moussa's performance for two reasons. In the first place, whether or no Moussa in fact held a red-hot iron bar without incurring any lesion of the skin or mucous membrane visible at the time by lamplight or next day by daylight, there is no doubt that his companions believe that the power to do this was suddenly given him. Yusuf, the son of the sheikh of the Qift Ababdeh, of whose honesty I have had much experience, was present at the time and had not a shadow of doubt as to the reality of what he had seen; he had heard of plenty of other instances, and he absolutely failed to see any difficulty in accepting the facts at their face value, or to sympathise with me in my doubts.

Hence, Mr. Mackay's experience at its lowest value is worth recording as an example of one method by which a reputation for holiness may be acquired in the Near East. But I hope that by putting this matter upon record I may help to bring about a result of greater value than this—namely, that my example may encourage observers among native races to study and describe the facts of all instances of the state, or states, which are commonly grouped under the titles of "ecstasy," "possession," and "shamanism," for there is at least *prima-facie* evidence suggesting that these three states in certain cases are due to "depersonalisation" or to "multiple personality," and are in many ways comparable with the examples studied and recorded by alienists and psychologists. Moreover, the accumulation and study of instances like the present, in which harmful substances are reported to fail to produce the lesions which in ordinary circumstances follow their action, seems to be the only way of testing the credibility of a number of unusual and "non-natural" events which are recorded as occurring among savage and civilised peoples at the present day.

[1] Mr. Hornblower tells me of an instance within his own knowledge in which a man was bitten by a snake while pulling down an old house. The man laughed, said he was a Rifa'i, and that the snake therefore could not hurt him; nevertheless, he died in a few hours.

[2] The bars were placed end on in the fire, and therefore one end got hot while the other was used as a handle. The iron was taken hold of at each end and held above the head like the small stick used by dancing girls in Egypt.

WEST CORNWALL INFIRMARY, PENZANCE.—Several young people in Penzance recently collected £100 for providing the West Cornwall Infirmary with the X ray apparatus, and last week it was presented to the institution.

# ROYAL SOCIETY OF MEDICINE.

## THE SOCIETY'S NEW HOUSE.

ON a site at the corner of Wimpole-street and Henrietta-street, Cavendish-square, a house is now being erected which will provide ample accommodation for the Royal Society of Medicine for many years to come, even if the society continues to increase, as it is confidently expected it will do. On this area of nearly 10,000 square feet a handsome building of classical design, by Mr. John Belcher, R.A., will have its main entrance in Henrietta-street and a second and commodious entrance from Wimpole-street.

The building, as recommended by the Council, and approved by the Fellows at a recent special general meeting, will consist of a large, well-lighted, and excellent basement, a ground floor, and three additional floors. On the ground floor will be a handsome and spacious vestibule, two meeting halls—one capable of holding about 500 persons, the other somewhat smaller holding about 150 persons—and patients' rooms (for both sexes), cloak rooms, cashier's and porters' rooms.

The whole of the first floor will be taken up by the library and by the offices of the secretary, editor, and clerks. The library will extend the whole length of the building, and will be 110 feet long, 28 feet wide, and 19 feet in height. The periodical room will be an annex extending back 21 feet from the library proper at its eastern end. The library will have a gallery; and a mezzanine room with additional tables for readers will open off the gallery, and extend back the whole depth of the building at the Wimpole-street end. The main part of the second floor will be occupied by the council room—over the centre of the library; and by two committee rooms—one over each end of the library—each of which will communicate with the council room. There will also be a tea and conversation room, and lavatories for Fellows. On the third floor there will be a museum; a room, properly fitted and equipped for examining specimens and for histological work; a smoking-room; and a tea and conversation room, and lavatories for lady Fellows. In the basement there will be dressing-rooms and lavatory, and storage for 250,000 volumes.

The financial position of the society is as follows: The debenture debt is much more than amply secured by the property in Hanover-square, and the rent received from the present leaseholders of that property not only covers the interest on the debenture debt, but provides over £1600 a year, without which the subscriptions of the Fellows and members would not be sufficient to enable the society to pay its working and ordinary expenses out of income. The site of the new house has been paid for by money realised by the sale of investments. It was decided by a resolution passed at a special general meeting of the Fellows in February, 1910, that an effort should be made to raise the whole amount of the cost of the building by means of voluntary gifts from the Fellows of the society, the members of the sections, and the friends of Fellows and members. Though

NEW BUILDING OF THE ROYAL SOCIETY OF MEDICINE
to be ready for occupation at the end of the present year.

£12,224 have been promised or given (by 614 out of 2313 Fellows, 112 out of 976 members, and by other subscribers), yet up to the present time only £7558 have actually been received by the treasurers. The Council, however, hopes that with the assistance of all, or many, of the Fellows who have not yet contributed, the whole amount — £30,000 —will be raised before the building is completed, as it is expected to be by December in this year.

As the building is rapidly being proceeded with and the builder's certificates of charges and the architect's fees are now having to be met, as the several stages of the work are reached, it would be a great assistance if the amounts promised and the donations and subscriptions which Fellows are intending to give, were forwarded to the treasurers as soon as possible. It is desirable that Fellows in considering the amount of their contribution to the building fund should bear in mind that before the amalgamation many of them belonged to several of the societies now amalgamated, and paid annual subscriptions of £5 5*s.* or more, some even as much as £10 10*s.* The inclusive annual subscription since the amalgamation is now only £3 3*s.*, and Fellows of the Royal Society of Medicine, besides receiving the costly and admirable volumes of "Proceedings," obtain much greater advantages than were formerly enjoyed by Fellows of the Royal Medical and Chirurgical Society, whether they were also members of one or more of the other societies or not.

# THE LONDON COUNTY COUNCIL AND MEDICAL AFFAIRS.

*Medical Inspection and Treatment of London School Children: Debate on the Reorganisation Proposals.*

AS indicated in THE LANCET of March 4th, p. 627, the proposals brought before the Education Committee of the London County Council on March 1st for the reorganisation of school medical work by placing Dr. J. Kerr definitely in the department of the education officer, Mr. R. Blair, led to an interesting debate. Members evidently found themselves on the horns of a dilemma; they were conscious of the disadvantages (pointed out in THE LANCET of Feb. 25th, p. 520) of placing the medical officer for education under a lay authority, and, on the other hand, they feared it would be difficult to secure coöperation with school managers, teachers, and local care committees if medical inspection and treatment were organised from the public health department of the Council. A proposal by the chairman of the Council's General Purposes Committee to make Dr. Kerr a chief officer of the Council received an equality of voting, the chairman not exercising his casting vote. We were not able to find space last week for this interesting debate.

Mr. R. A. BRAY opened the attack on the recommendations of the Children's Care Subcommittee by moving an amendment which would make Dr. Kerr directly responsible to the general medical officer, Sir Shirley Murphy, instead of to Mr. Blair. Mr. Bray said it was generally agreed that medical inspection and treatment must go together, and difficulty had arisen because the first named was under the control of the medical officer for education purposes and the second was under the direction of the education officer. He agreed that there must be close coöperation between Dr. Kerr and Mr. Blair, but close coöperation did not mean absorption. Surely Mr. Blair had enough to do without being responsible for work of which he had no first-hand knowledge. Mr. Bray claimed that his amendment meant comparatively little change because Dr. Kerr was already a member of the staff of the medical officer of the Council. If his proposal were carried the Education Committee would remain the authority, but the advantage would be that the local care committees would be brought into much closer relationship with the medical and nursing staffs. The proposal of the subcommittee, on the other hand, was contrary to the whole system of classification adopted by the Council. It was much more satisfactory to classify the staff by professions; thus one valuer attended to valuations for all branches of the Council's service; one solicitor was responsible for all legal work, whether it arose in the department of the tramways or of education. The same principle should be followed with regard to medical work, but instead it was proposed to set up a medical staff not under the medical officer but under the education officer. The recommendation meant breaking up the fundamental principle of committee work. Committee-men were not experts, but their duty was to judge the reports of experts and decide what action should be taken. That system was based on the principle that the committee got the reports of its experts pure. They wanted to know what the medical officer recommended, and not what the education officer recommended after consultation with the medical officer. The promise that the medical officer would have free access to the committee did not amount to very much. A subordinate officer could not be constantly bringing up reports differing from those of his chief. The result would be an intolerable position for the subordinate and his superior. It was of vital importance that the committee should get the pure undiluted reports of its medical officer because many of the questions to be decided had a medical and an educational side, and the committee needed to see the position from every point of view and not see both sides as the education officer saw them. Mr. Bray also said that at a time when it was becoming generally agreed that some greater unifying of the medical services of London was needed, the establishment of a new medical service was to be deprecated, especially when it was proposed to place it under the guidance of a layman. Medical inspection and treatment were only part of the medical supervision that children required. There was the immensely important part of supervision of the homes. This work was carried on for the most part by the medical officers to the borough councils, but the London County Council medical officer had very large powers with regard to the local health authorities. Insanitary houses were dealt with under by-laws made by the County Council, and the same remark applied to infectious diseases. Under the subcommittee's scheme this work was to be carried on through two separate departments.

*Objections to Public Health Committee Control.*

Miss SUSAN LAWRENCE objected to the amendment. She said Sir Shirley Murphy was a purely advisory official and Dr. Kerr was an administrative officer, yet the amendment proposed to place a great administrative work under a department which did not concern itself to any degree with questions of organisation. The Education Committee had to do with the child, not merely with regard to its school but as to its general health conditions. (Mr. BRAY: "Hear, hear.") Therefore, the medical officer for education purposes, who was concerned with the physical condition of the children as well as with treating them, should be an officer of the Education Committee. It was the machine of the school that gave them a hold on the child, and the Public Health Department would not be able easily to keep in touch with that machine. It was an extremely difficult question, but she thought the proposals of the subcommittee would make for greater efficiency.

The Rev. Dr. SCOTT LIDGETT feared that the Public Health Committee had not the experience that would enable it to preside over the genesis of a totally new way of dealing with the children in the schools. If the work was put under the public health medical officer they would alienate all those helpful influences in developing "the new science and practice of the care of the child" which the medical officer for education purposes was beginning to build up. At the present largely experimental stage this work should be kept free from the overshadowing influence of the public health department.

Mr. GILBERT JOHNSTONE, as a member and ex-chairman of the Public Health Committee, declared that the relationship which was formally maintained until recently between the public health medical officer and the medical officer for education purposes was a farce. The Public Health Committee had only an elementary knowledge of what the medical officer for education was doing. Only once during three years was his work brought before the committee.

The Rev. STEWART HEADLAM said he wanted the medical officer for education to be predominant, and all detail work to be left to Mr. Blair. Dr. Kerr should have a free hand to organise the medical side of the work, and he was reluctant to place him under the control of "the high people at County Hall." (The Education Department has offices of its own in a separate building.)

Mr. SHEPHEARD, deputy chairman of the Council, urged the committee to look at this matter from a general administrative point of view. The Council was the authority for education, and the organisation of the education staff must follow the general lines laid down by the Council. The subcommittee's proposal was contrary to the principles formulated by the Council in other departments on several recent occasions. If the educational medical work was placed under the Public Health Department he believed the head of that department would leave Dr. Kerr a pretty free hand.

Miss ADLER said that more and more the Education Committee was coming to deal with the whole lives of young people, and medical inspection and treatment should be retained under its control.

Mr. FREEMAN BARRETT, chairman of the Public Health Committee, thought the proposal of the subcommittee was contrary to the policy of the Council and would be disapproved. The arrangements adopted for medical inspection and treatment during the past year or 18 months had been very unsatisfactory indeed. He did not in the least blame Dr. Kerr—rather he sympathised with him because he knew Dr. Kerr might have been desirous of pursuing one line and have been held in check by members of the Education Committee. It was not very satisfactory to find the Board of Education again blaming them in regard to inspection and treatment. Medical questions should be placed entirely in the hands of medical men. If Mr. Blair were pla ed in supreme control of the Education Department difficulties would occur when questions of a medical character arose on which only a medical opinion was of any value.

Mr. HOBSON thought it would be a fatal error to place the treatment of many thousands of children under a lay officer, in conjunction with whose administration all sorts of difficulties would arise in relation to medical etiquette.

On a division Mr. Bray's amendment to make Dr. Kerr responsible to Sir Shirley Murphy was lost by 19 votes to 10.

*Education Medical Officer a Chief Officer.*

Mr. ERNEST GRAY, chairman of the General Purposes Committee of the Council, which has to revise all administrative proposals by other committees, then moved the following amendment:—

That the medical inspection and treatment of school children be placed under the control of the medical officer for education purposes, and that he be directly responsible to the Education Committee and be a chief officer of the Council.

This amendment was put to the vote forthwith and there were 14 votes for and 14 against. The chairman declined to exercise his casting vote and the amendment fell to the ground.

The reference back of the whole question was then suggested, but Mr. F. R. ANDERTON, chairman of the subcommittee, said it was important that the report should go forward, because until a conclusion was arrived at the consideration of schemes for supplying the deficiencies in the medical treatment scheme pointed out by the Board of Education would have to be suspended. The committee had to meet the objections of the Board of Education within a reasonable time.

Mr. GRAY said everyone was struggling with an illogical position. Medical treatment must be swallowed up in the public health department if one scheme were carried, or a layman must be placed in authority over Dr. Kerr if the other scheme were put into operation. The committee might overcome the difficulty by taking a step which he believed it would be driven to take ultimately if they did not take it now. School medical work would grow and it would demand the services of a chief officer of the Council. In his opinion it could, and should, be dissociated from the ordinary public health work. That was why he moved his amendment: to test the feeling of the committee. It received more support than he thought possible, and that method of dealing with the difficulty should have further consideration in subcommittee.

Mr. JOHNSTONE objected that Mr. Gray's proposal was sprung on the committee without discussion.

Mr. BRAY and the Chairman of the Committee both urged the desirability of coming to an immediate decision. The Chairman remarked that the whole question of reorganisation of medical treatment was being held up, and he regarded this as a matter of extreme urgency.

Only seven members voted for the reference back and the subcommittee's recommendation to place the medical officer for education purposes under the control of the education officer was then carried by 19 votes to 11.

*Notification of Chicken-pox.*

On Tuesday, March 14th, on the recommendation of the Public Health Committee, the London County Council decided to make chicken-pox a notifiable disease under the Public Health (London) Act, 1891, for three calendar months from March 22nd, 1911. The committee stated that slight cases of small-pox were sometimes mistaken for chicken-pox and so were not isolated as early as they would have been had the real nature of the disease been recognised.

## THE METROPOLITAN HOSPITAL SUNDAY FUND.

THE Lord Mayor presided on March 10th over a meeting of the Council of the Metropolitan Hospital Sunday Fund, which was convened for the purpose of considering a recommendation of the Finance Committee with reference to the appointment of new trustees, and also of discussing the question of the contributions of Sunday cinematograph shows to the funds of hospitals which participated in the awards of the Metropolitan Hospital Sunday Fund.

With regard to the question of trustees, Mr. John Hale explained that the Lord Mayor, the Governor of the Bank of England, and the City Chamberlain for the time being were the trustees of the Fund, but although that arrangement had worked well the continual transference of securities was a source of expense which could be obviated by the appointment of permanent trustees. It was subsequently agreed that Mr. J. Hale, Mr. J. H. Buxton, Sir John Bell, and Sir Ernest Tritton should be appointed trustees, and that powers should be sought for this alteration.

*Sunday Cinematograph Entertainments.*

Archdeacon SINCLAIR then moved the adoption of the recommendation of the General Purposes Committee, which had recently debated this subject. The recommendation read as follows:—

That the Council has fully considered the recommendations of the General Purposes Committee on the subject of Sunday cinematograph entertainments run by hospitals, as well as the proposal of certain places of worship to earmark their collections for hospitals which do not participate in the proceeds of such shows, and while not expressing any opinion upon the expediency or otherwise of Sunday entertainments as such, disapproves of hospitals receiving grants from this Fund (which consists mainly of church collections) being concerned in any movement which is contrary to the spirit of its supporters. The Council further resolves that in the event of the collections for the Fund suffering any diminution which may be fairly attributable to the continuance of these entertainments, as aforesaid, it shall be a recommendation to the Committee of Distribution to take the same into consideration when making their awards for the year. It is ordered that a copy of this resolution be forwarded to the committee of management of each of the hospitals concerned.

Archdeacon Sinclair said that three or four of the leading churches in the metropolitan area—both Church of England and Nonconformist—were so displeased at the method by which four hospitals were receiving part of their funds that they asked the Council to earmark their contributions for hospitals which did not employ that method. The London Hospital, the Evelina Hospital for Sick Children, and two others had held entertainments at electric theatres on Sunday afternoons. The London Hospital made about £1300 a year in this way. Two sets of people objected to the holding of these entertainments on Sunday—those who regarded the proceeding as a serious evasion of the law and those who regarded it as an infringement of the day of rest by which the customs of this country had hitherto been regulated. The churches which made the objections were not in the least degree jealous, because those churches were always full. The committee felt bound to safeguard the interests of the Fund and to do all in their power to protect the scruples of those congregations and preserve the integrity and harmony of the Hospital Fund, so long and so happily maintained. They did not express any condemnation of the electric theatres. That was a matter for the public and the London County Council, but as this particular method of raising money had caused a scandal amongst certain of their constituents, they wished to show that they dissociated themselves from it.

Lord CHEYLESMORE seconded the adoption of the recommendation. He thought that to recognise Sunday cinematograph entertainments would be most detrimental to the interests of the Fund, though he had nothing to say against them as entertainments. It should be remembered that the bulk of the money collected by the Fund came from the clergy and the people who attended places of worship. The Fund should hold to the clergy and their congregations.

The Hon. SYDNEY HOLLAND complained that although he had been invited by the General Purposes Committee to discuss the matter with them at a certain hour on a particular day, when he arrived, even before the time appointed, the matter had been decided and the recommendation printed. He moved as an amendment that the Council take no action in the matter. The London Hospital received between £1200 and £1400 a year from Sunday cinematograph entertainments. He thought the public would dissent from the narrow-minded policy recommended by the committee. If that recommendation was adopted it would mean that the money collected by the Hospital Sunday Fund would not go to the hospitals that were best managed, but to those institutions whose managers were most pliable to dictation. The principle of the Fund hitherto had been that it would not interfere with the way in which a hospital got its money, but would interfere with the way in which it was spent. The poor people who attended cinematograph entertainments were people who would not contribute to the Fund. If the proposed policy was pursued the next step would be for clergymen who were teetotalers to allocate their subscriptions to hospitals where no drink was given. There would be no end to the number of views that would be pressed upon the Council of the Fund. The proposal they were considering would not be popular with the people nor with all the clergy.

The Rev. H. R. GAMBLE, seconding Mr. Holland's amendment, thought that by accepting the committee's report the Council would be entering upon an extremely dangerous course the consequences of which they could not see. It was inexpedient that the sources of the money received should be investigated, and if some churches allocated their collections to one hospital and some to another it would lead to an exceedingly dangerous warfare. It was in the ultimate interests of the Fund that he asked the Council to hesitate before coming to a conclusion in the matter.

Sir A. PEARCE GOULD, who supported the resolution, said that Mr. Holland was departing from the voluntary system. He was earning money for the hospitals. If the principle that hospitals could be supported by other than voluntary contributions were once admitted the support of hospitals by the rates would follow. Why did Mr. Holland stop at Sunday shows? why did he not run public-houses? (Mr. HOLLAND: I do.) If that were done the public would say that hospitals could be supported as business institutions, and would cease to contribute to them. It was impossible to close one's eyes to the fact that the hospitals had been supported by those who were interested in religion and in the religious movements of the country.

The Rev. C. H GRUNDY, speaking in behalf of Mr. Holland's amendment, hoped that the Council would have nothing whatever to do with a question that did not concern them.

The amendment, "That this Council resolves to take no action in the matter," on being put by the CHAIRMAN, was lost by 10 votes to 19.

The Rev. C. H. GRUNDY then moved the previous question, which was also lost.

Deputy M. WALLACE moved that the matter be referred back in order that Mr. Holland might have an opportunity of discussing the matter with the committee.

Sir A. PEARCE GOULD pointed out that Mr. Holland had already fully discussed the matter, and Mr. HOLLAND then appealed to the Lord Mayor, who was present at the committee meeting, as to the truth of his (Mr. Holland's) statement with regard to the consideration of the recommendation before Mr. Holland's arrival. The LORD MAYOR admitted that Mr. Holland was technically correct, but said that the meeting in question had been reopened to allow Mr. Holland to discuss the matter.

Mr. HOLLAND opposed the sending back of the report to the committee as they had already made up their minds on the matter.

It was, however, after some discussion decided to refer the report back.

# VITAL STATISTICS.

## HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns 8180 births and 4911 deaths were registered during the week ending March 11th. The annual rate of mortality in these towns, which had been equal to 17·6, 17·2, 16·2, and 15·3 per 1000 in the four preceding weeks, further declined to 14·9 in the week under notice. During the first ten weeks of the current quarter the death-rate in these 77 towns averaged 16·0 per 1000, and the mean recorded rate in London during the same period was 15·9. The annual death-rates during last week ranged from 7·6 in Wallasey, 7·7 in Handsworth and King's Norton, and 8·1 in West Hartlepool, to 22·4 in Devonport, 22·6 in Sheffield, 27·5 in Dewsbury, and 28·3 in Middlesbrough. The 4911 deaths from all causes in the 77 towns showed a further decline of 129 from the numbers returned in the four preceding weeks, and included 702 which were referred to the principal epidemic diseases, against numbers increasing from 477 to 663 in the five preceding weeks; of these 702 deaths, 474 resulted from measles, 80 from whooping-cough, 56 from diphtheria, 49 from diarrhœa, 24 from scarlet fever, 13 from enteric fever, and 6 from small-pox. The fatal cases of measles, which had steadily increased from 160 to 397 in the first nine weeks of the current quarter, further rose last week to 474; they caused the highest annual death-rates of 3·4 in Rochdale, 3·9 in Wigan, 4·6 in Leyton, 9·1 in Devonport, and 10·3 in Sheffield. The deaths from whooping-cough, which had been 91 and 108 in the two preceding weeks, declined to 80 last week; the highest death-rates from this disease last week were 1·1 in Leyton and in Wigan, 1·9 in Middlesbrough, and 2·0 in Dewsbury. The 56 fatal cases of diphtheria showed a decline of 8 from the number in the previous week, and included 15 which were recorded in London and its suburban districts, 4 in Birmingham, 3 in Bolton, 3 in Barrow-in-Furness, 5 in Leeds, and 3 in Gateshead. The deaths of infants under 2 years of age attributed to diarrhœa, which had been 53 in each of the two preceding weeks, declined to 49 last week, and were fewer than in any previous week of this year. The 24 fatal cases of scarlet fever showed a further slight decline from the number in the two previous weeks; 4 occurred in London and its suburban districts, 4 in Liverpool, and 2 both in Wolverhampton and in Sheffield. The 13 deaths referred to enteric fever also showed a decline; 2 were registered both in Manchester and in Nottingham. Six deaths from small-pox were recorded in London, 3 being of young children and 3 of adults; 10 deaths from this disease have occurred in the Metropolitan Asylums Hospitals during the past two weeks. The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospital, which had been 1276, 1242, and 1197 in the three preceding weeks, had further declined to 1166 on Saturday last; 120 new cases of this disease were admitted to these hospitals during last week, against 166, 138, and 129 in the three preceding weeks. These metropolitan hospitals also contained on Saturday last 944 cases of diphtheria, 748 of measles, 253 of whooping-cough, 47 of small-pox, and 23 of enteric fever. The 1391 deaths from all causes in London last week, showing a further slight decline from recent weekly numbers, included 328 which were referred to diseases of the respiratory system, against 421, 395, and 318 in the three preceding weeks. In the 77 towns 142 deaths from different forms of violence were registered during last week, showing a further decline from the numbers in recent weeks; and 342 inquest cases were recorded. The causes of 38, or 0·8 per cent., of the deaths registered during the week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, Leicester, and in 50 other smaller towns; the 38 uncertified causes of death in the 77 towns last week included 9 in Birmingham, 4 in Liverpool, 4 in Sheffield, 3 in Portsmouth, and 2 in St. Helens.

## HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 894 births and 583 deaths were registered during the week ending March 11th. The annual rate of mortality in these towns, which had been equal to 19 8, 19·0, 17·4, and 16·9 per 1000 in the four preceding weeks, further declined to 15·9 in the week under notice. During the first ten weeks of the current quarter the death-rate in these towns averaged 16·9 per 1000, and exceeded by 0·9 the mean rate during the same period in the 77 English towns. The annual death-rates last week in the eight Scotch towns ranged from 11·0 and 11·3 in Paisley and Aberdeen to 24·9 in Perth and 25·3 in Greenock. The 583 deaths from all causes in the eight towns last week showed a further decline of 38 from the numbers returned in recent weeks, and included 60 which were referred to the principal epidemic diseases, against 76 and 57 in the two previous weeks; these 60 deaths were equal to an annual rate of 1·6 per 1000, being 0·5 below the rate from the same diseases in the 77 English towns; the highest rates from these diseases last week in the Scotch towns were 2·7 in Dundee and 3·0 in Leith. Of these 60 deaths from the principal epidemic diseases, 36 resulted from whooping-cough, 7 from diarrhœa, 5 from measles, 5 from diphtheria, 4 from scarlet fever, and 3 from enteric fever, but not one from small-pox. The fatal cases of whooping-cough, which had been 45, 39, and 32 in the three preceding weeks, rose again to 36 last week, and included 19 in Glasgow, 8 in Dundee, 4 in Leith, and 2 in in Edinburgh and in Paisley. The 7 deaths attributed to diarrhœa were fewer by 5 than the number in the previous week, and were all of infants under 2 years of age. The 5 fatal cases of diphtheria corresponded with the number in the previous week, including 2 in Edinburgh. The 5 deaths from measles, of which 3 occurred in Glasgow and 2 in Edinburgh, exceeded those

in the previous week by 3. The 4 fatal cases of scarlet fever, of which 2 occurred in Edinburgh, corresponded with the number in the previous week. The 3 deaths referred to enteric fever included 2 in Glasgow and 1 in Leith. The deaths referred to diseases of the respiratory system in the eight towns, which had been 181, 139, and 118 in the three preceding weeks, further declined last week to 108. The 20 deaths referred to different forms of violence exceeded the number in the previous week by 5; and 177 of the 583 deaths from all causes in the eight towns, or 30 per cent., occurred in public institutions. The causes of 15, or 2·6 per cent., of the deaths registered during the week were not certified or not stated; in the 77 English towns last week the proportion of uncertified causes of death did not exceed 0·8 per cent.

### HEALTH OF IRISH TOWNS.

In the 22 town districts of Ireland, having an estimated population of 1,163,596 persons, 627 births and 431 deaths were registered during the week ending March 11th. The annual rate of mortality in these towns, which had declined in the four preceding weeks from 24·1 to 20·4 per 1000, further fell to 19·3 in the week under notice. During the first ten weeks of the current quarter the annual death-rate in these 22 towns averaged 20·7 per 1000; the rate during the same period did not exceed 16·0 in the 77 English towns, and 16·9 in the eight Scotch towns. The annual death-rate during last week was equal to 21·0 in Dublin, 15·4 in Belfast, 27·4 in Cork, 15·4 in Londonderry, 24·6 in Limerick, and 17·5 in Waterford; in the 16 smallest of the Irish towns the mean annual death-rate last week was equal to 20·8 per 1000. The 431 deaths from all causes in the 22 towns last week showed a further decline of 24 from recent weekly numbers, and included 26 which were referred to the principal epidemic diseases, against 41 and 25 in the two preceding weeks; these 26 deaths were equal to an annual rate of 1·2 per 1000, which was 0·9 below the mean rate from the same diseases in the 77 English towns. Of these 26 deaths in the Irish towns from the principal epidemic diseases, 10 resulted from whooping-cough, 8 from measles, 3 from enteric fever, 3 from diarrhœa, and 2 from diphtheria, but not one from scarlet fever or small-pox. The 10 fatal cases of whooping-cough showed a decline of 12 from the number in the previous week, including 3 in Dublin and 2 in Newtownards. The 7 fatal cases of measles, the 3 of enteric fever, and the 2 of diphtheria were all recorded in Dublin. Of the 3 deaths attributed to diarrhœa, 2 were of infants and 1 of an adult. The deaths in the 22 towns referred to diseases of the respiratory system, which had declined in the four preceding weeks from 141 to 108, further fell last week to 100. Of the 441 deaths from all causes last week, 133, or 31 per cent., were recorded in public institutions. The causes of 19, or 4·4 per cent., of the deaths in the 22 towns last week were not certified either by a registered medical practitioner or by a coroner after inquest; the proportion of uncertified causes of death last week did not exceed 0·8 per cent. in the 77 English towns, and 2·6 per cent. in the eight principal Scotch towns.

## THE SERVICES.

### ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet-Surgeons: T. W. Philip to the *President*, additional, for Greenwich Hospital School and Royal Naval College, temporary; J. H Stenhouse to the *Africa;* A. G. Andrews to the *Egmont*, additional, for Malta Dockyard; E. B. Townsend to the *Superb;* J. Menary to the Chatham Division, R M.L.I.; H. B. Beatty, G. A. Waters, R. Hill, M V.O., A. Gaskell, B. F. Parish, and L. Kilroy to the *President*, additional, for three months' hospital course; F. D. Lumley to the *Defence*; H. C. Arathoon to the *Formidable*, J. K. Robinson to the *Cæsar*, and J. A. Keogh to the *Cochrane*, all on recommissioning. Staff-Surgeons: W. E. Mathew, G. Ross, and A. X. Lavertine to the *President*, additional, for three months' hospital course; L. E. Darnell to the *Mercury*, additional; J. H. Lightfoot to the *Vivid*, additional, for disposal; R. S. Osborne to the *Berwick;* H. Huskinson to the *Bulwark;* A. T. Gailleton to the *Halcyon*, on recommissioning; G. E. Macleod to the *Dreadnought*, temporary, on recommissioning; and J. A. Forrest to the *Andromache*. Surgeons: A. L. Robinson to the *Africa;* P. M. Rivaz to the *President*, additional, for three months' hospital course; G. A. Bradshaw to the *Formidable*, F. M. V. Smith to the *Cochrane*, both on recommissioning; and H. Cooper to the *Pomone*, additional, lent, for Dartmouth College, temporary.

### ARMY MEDICAL SERVICE.

Colonel Arthur E. J. Croly is placed on retired pay (dated March 9th, 1911). Lieutenant-Colonel Edmund J. E. Risk, from the Royal Army Medical Corps, to be Colonel, *vice* A. E. J. Croly (dated March 9th, 1911).

Surgeon-General Sir Thomas J. Gallwey, K.C.M.G., C.B., retires on retired pay (dated March 15th, 1911).

Colonel George W. Robinson to be Surgeon-General, vice Sir T. J. Gallwey (dated March 15th, 1911).

Lieutenant-Colonel William G. Birrell, from the Royal Army Medical Corps, to be Colonel, vice G. W. Robinson (dated March 15th, 1911).

### ROYAL ARMY MEDICAL CORPS.

Lieutenant Reginald C. Galgey resigns his commission (dated March 11th, 1911).

Colonel W. G. Macpherson, C.M.G., from Malta, has taken over duty as Principal Medical Officer of the Fourth (Quetta) Division, India. Colonel E. Butt, Principal Medical Officer of the Presidency and Assam Brigades, has been transferred from Darjeeling to Calcutta. Lieutenant-Colonel S. Westcott, C.M.G., commanding the Station Hospital at Mhow, has been selected to command the Station Hospital at Chakrata. Lieutenant-Colonel N. Manders, Senior Medical Officer in Ceylon, has been selected for the higher rate of pay under Article 317 of the Royal Warrant. Lieutenant-Colonel R. H. Hall, from Colchester, has taken over duty as Senior Medical Officer at Bermuda. Lieutenant-Colonel S. R. Wills, commanding the Station Hospital at Agra, has been granted eight months' leave of absence from India. Lieutenant-Colonel H. H. Brown has been transferred from Murree to Rawal Pindi. Major H. I. Pocock, commanding the Military Hospital at Nowshera, has been granted six months' leave of absence in India. Major E. G. Browne has taken over charge of the Station Hospital at Delhi. Major D. D. Shanahan has been appointed Staff Officer for Medical Mobilisation Stores, Ninth (Secunderabad) Division, in succession to Major H. A. Hinge, tour-expired. Major A. Pearse, at present serving at Chatham, has been noted for appointment as Senior Medical Officer, West Africa. Major G. J. Buchanan, from Chaubutha, has taken up duty at Agra. Major E. M. Morphew, commanding the Station Hospital at Roorke, has been granted eight months' leave of absence home from India. Major H. S. Thurston, from the London District, has joined for duty at Malta. Major G. A. Moore has been transferred from Woolwich to Chatham. Major E. B. Steel, commanding the Military Hospital at Neemuch, has been granted leave of absence to Sept. 30th next. Major E. W. Slayter, from Wellington, has been appointed to command the Station Hospital at Bellary. Major A. E. Milner, from Tidworth Park, has joined for duty at Birmingham. Major G. M. Goldsmith, staff surgeon, Burma Division, has been granted eight months' leave of absence home from India with effect from March 15th. Captain J. H. R. Winder has been transferred from Shorncliffe for duty in the Aldershot Command. Captain J. A. Bennett, from Mhow, has been granted six months' leave of absence home. Captain J. Fairbairn, from Glasgow, has taken up duty at Sierra Leone. Captain J. G. Gill, commanding the Station Hospital at Cherat, has been granted six months' leave of absence home from India. Captain B. Johnson, from Wellington, has been appointed to command the Section Hospital, St. Thomas's Mount, Madras. Captain W. F. M. Loughnan has been transferred from Amritsar to Bareilly. Captain R. E. U. Newman, from Kuldanna, has joined at Rawal Pindi. Captain J. T. McEntire, from the Irish Command, has been posted to Newcastle. Lieutenant D. H. C. MacArthur, from Rawal Pindi, has taken up duty at Ambala Cantonment. Lieutenant A. T. J. McCreery has been transferred from Birmingham to Bulford. Lieutenant F. H. Somers-Gardner, from Pontypridd, has joined at Cosham.

### INDIAN MEDICAL SERVICE.

Lieutenant-Colonel S. H. Henderson, superintendent of the Central Prison at Agra, has been appointed by His Honour the Lieutenant Governor of the United Provinces to officiate as Inspector-General of Prisons in the United Provinces during the absence on leave of the Honourable Lieutenant-Colonel C. Mactaggart. Lieutenant-Colonel W. Vost, on return from leave, has been appointed Civil Surgeon at Saharanpur. Lieutenant-Colonel W. D. Sutherland, civil surgeon at Sangor, Central Provinces, has been granted three months' privilege leave. On return from combined leave Lieutenant-Colonel H. E. Banatvala has been placed on special duty at Nagpur, under the orders of the Inspector-General of Civil Hospitals in the Central Provinces. Major B. H. Deare, civil surgeon of Hazaribagh, on return from leave, has been appointed Civil Surgeon at Darjeeling. Major R. H. Price has been appointed Specialist in Midwifery and Diseases of Women and Children to the Fourth (Quetta) Division. Major J. L. Macrae has been confirmed in the appointment of Civil Surgeon of Coorg. The services of Major W. D. Hayward have been placed permanently at the disposal of the Army Department as Medical Storekeeper to the Government of India at Calcutta. Captain L. Reynolds has arrived home on leave of absence from India. Captain A. W. Overbeck-Wright, Supernumerary Superintendent of the Central Prison at Agra, has been appointed to officiate as Superintendent in succession to Lieutenant-Colonel S. H. Henderson. Captain O. St. J. Moses has taken over duty as Police Surgeon at Calcutta during the absence of Major W. D. Hayward. Captain H. Buckley has been appointed to the medical charge of Manipur State. Captain C. Dykes, civil surgeon of Saharanpur, has been placed in charge of plague operations in the Ghazipur, Azmgarh, and Ballia Districts. Captain W. H. Leonard, attached as medical officer to the 55th Sikhs, has been granted eight months' leave of absence from India. Captain H. C. Brown has been appointed Specialist in the Prevention of Disease to the Jullundur Brigade. Captain H. A. Williams, D.S.O., resident medical officer of the general hospital at Rangoon, has been granted two years' furlough and study leave. Lieutenant R. B. Lloyd, officiating medical officer of the 58th Rifles, has been transferred to the 31st Lancers and attached for duty.

### TERRITORIAL FORCE.

*Royal Army Medical Corps.*

1st South Western Mounted Brigade Field Ambulance, Royal Army Medical Corps: Captain Samuel Maclean, from the list of officers attached to units other than medical units, to be Captain (dated Dec. 28th, 1910).

2nd South Midland Field Ambulance, Royal Army Medical Corps: Captain Seymour Gilbert Barling, from the 1st South Midland Field Ambulance, Royal Army Medical Corps, to be Major (dated March 11th, 1911). Captain George William Craig, from the 1st South Midland Field Ambulance, Royal Army Medical Corps, to be Captain (dated March 11th, 1911).

### DEATHS IN THE SERVICES.

Captain William Harold Gillatt, R.A.M.C., at Cairo on March 8th. He entered the service as lieutenant in 1906.

Brigade-Surgeon Thomas Turville Gardner, retired pay, late Army Medical Department, on Feb. 18th, at Engalee, East Grinstead. He entered the service in 1858 as assistant surgeon, was promoted to surgeon-major in 1873, and retired with the honorary rank of brigade-surgeon in 1881.

### JOURNAL OF THE ROYAL ARMY MEDICAL CORPS.

In the March issue of this journal Major W. H. Horrocks contributes a long paper on the Viability and Possible Variation of the Bacillus Typhosus, his experiments seemingly confirming the opinion that the viability of the B. typhosus is of short duration. The value of tuberculin in the treatment of tuberculous affections is discussed in a paper by Lieutenant-Colonel F. H. Treherne, who gives the result of 34 cases, most of which received benefit from the treatment, and in no case can the treatment be said to have been a failure. Captain W. Byam writes on Malaria in Kassala in 1909, and Major M. Sykes, of the 5th Battalion, Yorkshire Regiment, makes an interesting report on a forced march, concerning which Lieutenant-Colonel C. H. Melville contributes a short appreciatory note. The needs of ambulance units are again met by a note on Improvised Stretchers from the pen of Colonel H. E. R. James. The first part of an abridged report of a tour from Freetown to Monrovia through the Protectorate of Sierra Leone and Liberia, by Major A. Pearse, makes very interesting reading; as does also an illustrated account of the Eland of the Bahr-el-Ghazal Province, contributed by Major H. Ensor, D.S.O.

### THE OUTBREAK OF MEASLES AT DARTMOUTH.

Surgeon B. Pick, R.N., is suffering from measles, and 21 fresh cases have occurred at the Royal Naval College.

# Correspondence.

"Audi alteram partem."

## CHARLES BELL AND THE MOTOR AND SENSORY FUNCTIONS OF SPINAL NERVES.

*To the Editor of* THE LANCET.

SIR,—It will greatly assist to settle the claims of Sir Charles Bell as the discoverer of the functions of the roots of the spinal nerves if it be fully admitted that by July 22nd, 1822, Magendie had designed and carried out a series of experiments which demonstrated beyond any further question that the "anterior roots are destined for motion while the posterior belong more particularly to sensation." Professor Waller in assigning the full merit of the discovery to Magendie leaves out of consideration certain essential circumstances. At the end of August, 1821,[1] Mr. John Shaw, Bell's brother-in-law and assistant, went to Paris; amongst the men he met there and to whom he explained the experiments and discoveries of the Windmill-street School was Magendie.[2] How much Magendie was impressed by Bell's work can be judged from two circumstances: first, he sent a message and afterwards a letter[3] to the English surgeon asking for a short account of his work in order that a "prize medal" might be awarded him; secondly, he published[4] at once (October, 1821) an account of Bell's theory and discoveries, founded on the communication made to him by Mr. Shaw. From that account we learn that he proceeded there and then to repeat Bell's experiments on the facial nerve, and on the fifth nerve, verifying the general accuracy of Shaw's communication. Further, he was placed in possession of two important facts: that the roots of the spinal nerves were different in function, and that the fifth cranial nerve belonged to the spinal series, from which it naturally followed that the results obtained by Bell's experiments on the fifth cranial nerve might be transferred to the spinal nerves. In 1821 Magendie's experimental work was connected with the mechanism of the circulation; in 1822 it concerned the results of sections of nerves. Dr. Leonard Guthrie[5] has already given an account of Magendie's surprise when after publishing the results of his first experiments in July, 1822, he received a note from "M. Schaw" claiming priority for his master, "M. Ch. Bell." From the facts narrated here there is no question as to who was the pioneer in opening up a scientific knowledge of the nervous system—it was Bell and not Magendie. An English student, however, on reading Professor Waller's "Introduction to Human Physiology," must conclude that Bell had no part in the discovery of the function of nerve roots.

The real point of difference, as far as concerns Professor Waller and myself, is in the interpretation of what Sir Charles Bell meant by "cerebral" and "cerebellar." By "cerebral" Professor Waller understands him to mean motor and sensory nerve fibres, and by "cerebellar" fibres "which serve to govern vital actions." On the other hand, I translate "cerebral" to mean motor and "cerebellar" to mean

[1] Letters of Sir Charles Bell, London, 1870, p. 271.
[2] Narrative of the Discoveries of Sir Charles Bell, by Alex. Shaw, London, 1839.

[5] THE LANCET, March 11th, p. 697.

sensory, for the following reasons. Sir Charles Bell's inquiry was primarily devised to find out the function of the cerebrum and cerebellum. He traced the connexion of cerebrum to the anterior columns of the spinal cord through the pyramidal tracts and the relationship of the cerebellum to the posterior columns by means of its inferior peduncles. From the very commencement of his investigations in 1807 he recognised the difference between what we now call motor and sensory nerves, and knowing that the cerebrum received and gave out both kinds of fibres expected, when he came to experiment on the anterior roots and anterior columns, to find evidence of both kinds of fibres. What he actually found is most clearly and briefly related in his letter to his brother George (March 12th, 1810):—

> It occurred to me that as there were four grand divisions of the brain, so were there four grand divisions of the spinal marrow; first, a lateral (bilateral) division; then a division into the back and fore-part (dorsal and ventral divisions). Next it occurred to me that all the spinal nerves had within the sheath of the spinal marrow two roots—one from the back part, another from before. Whenever this occurred to me I thought that I had obtained a method of inquiry into the function of the parts of the brain.
>
> *Experiment 1.*—I opened the spine and pricked and injured the posterior filaments of the nerves—no motion of the muscles followed. I then touched the *anterior* division—immediately the parts were convulsed.
>
> *Experiment 2.*—I now destroyed the posterior part of the spinal marrow by the point of a needle—no convulsive movements followed. I injured the anterior part and the animal was convulsed. It is almost superfluous to say that the part of the spinal marrow having sensibility comes from the cerebrum; the posterior and insensible part of the marrow belongs to the cerebellum.
>
> Taking these facts as they stand, is it not most curious that there should be thus established a distinction in the parts of a nerve and that a nerve should be insensible?

No statement could be clearer as to the function of the roots. At this early date Bell recognised that the spinal roots were different in function and that the anterior root was "sensible" (motor in modern terminology) in function and the posterior "insensible," or sensory, for at this date Bell had concluded that there were two kinds of nerve, those carrying impulses to the brain and those carrying impulses from it (afferent and efferent, in the modern sense). The results of these experiments were accurately noted. The anterior or "cerebral" part of the spinal cord and its corresponding root did not yield quite the results he expected; he expected both motor and sensory disturbance, and only obtained motor. The results, however, gave him a clue to one function of the cerebellum, and shows how clearly he recognised the afferent or sensory nature of the posterior root. He had inferred that muscles were supplied with afferent as well as efferent nerves, and were coördinated while in action by impulses streaming in by the afferent nerves. He assigns to the cerebellum the function of "controlling the actions of the bodily frame." That followed as an inference from his discovery that the posterior roots and posterior columns of the cord were "insensible," "silent," or "secret." It will be thus seen how unjust Professor Waller is to his countryman when he infers that Bell found that "the anterior or 'cerebral' roots are motor and sensory, and that the posterior or cerebellar roots serve to govern vital actions." Bell expected them to be so in function, but when he applied the test of experiment he found the one sensible (motor) and the other insensible (sensory).

I have no wish, indeed it would be impossible for me, to obtain a dialectical victory over a brilliant exponent of the methods of Magendie, nor do I desire in any way to touch on the great and well-founded reputation of Sir Charles Bell. But I do wish again to emphasise the importance of his method. From a consideration of the anatomy of the brain and nerves he sought to formulate a theory which would account for the arrangement of parts. He proceeded to test his theory by observation and experiment year after year from 1807 to 1821, his only means of publication being his daily lectures. The discovery of the function of the spinal roots was merely an incident in the prosecution of a great endeavour. Since Bell's time anatomy and physiology have been divorced to their mutual loss, for I am certain no great discovery can be made in the mechanism of the animal body unless the problems suggested by a consideration of structure are resolved by the methods of experimental physiology.

I am, Sir, yours faithfully,

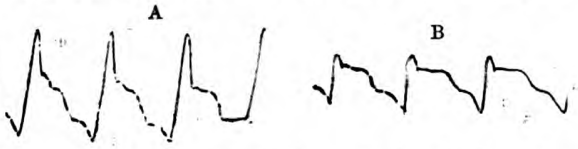
ARTHUR KEITH.

Royal College of Surgeons of England, London, W.C., March 9th, 1911.

## THE SPHYGMOMANOMETER AND THE SPHYGMOGRAPH IN RELATION TO THE MEASUREMENT OF ARTERIAL BLOOD PRESSURES.

*To the Editor of* THE LANCET.

SIR,—Dr. C. O. Hawthorne, in his interesting article in THE LANCET of Feb. 18th on this subject, pointed out how the readings of the two instruments may give diametrically opposite results interpreted in the terms of "high blood pressure" and "low blood pressure"; that the sphygmomanometer may give a low record—e.g., 75 mm. of Hg of blood pressure—whilst at the same time the sphygmograph may indicate what has hitherto been interpreted as a "high-tension" record, and, conversely, that a high reading of the sphygmomanometer may coincide with a "low-tension" picture on the sphygmograph taken at the same time, and he points out the difficulty of reconciling the readings of the two instruments. He attempts to do this by drawing attention to the varying *duration* of the "pulse pressure" in different cases, and he thinks the type of sphygmographic tracing which has hitherto been called a "high-tension" one should really be named the "well-sustained blood pressure" record, and the "low-tension" sphygmogram should be called the "ill-sustained blood pressure" record, and he says "then all apparent contradictions of the sphygmomanometer and the sphygmograph disappear"; but I venture to think this is not the whole story or even the true explanation. These two sphygmograms were taken from the same patient at the same time on the same piece of paper as it was running through the instrument, yet how different they are. A answers to the



description of a "low-tension" or an "ill-sustained" pulse, B corresponds to that of a "high-tension" or "well-sustained" pulse. How is this to be explained? The blood pressure did not vary and it is inconceivable that the *duration* of the rise of pressure varied so quickly; moreover, these "well-sustained" and "ill-sustained" rises of pressure in the sphygmograms can be produced at will in the same pulse within a few seconds of each other, and this simply by *varying the pressure of the sphygmograph lever* on the artery—the apparent "ill-sustained" pulse is produced by light pressure of the lever and the "well-sustained" pulse by heavier pressure. In fact, the sphygmograph as at present made is useless as an exact scientific instrument for indicating either the "tension" of a pulse or the "well" or "ill-sustained" blood pressure, it simply records the whim of the operator.

I am, Sir, yours faithfully,

Leicester. REGINALD PRATT.

## MUSCULAR SPASM IN CARIES OF THE SPINE.

*To the Editor of* THE LANCET.

SIR,—I have no wish to minimise the value of the excellent practical work done by Mr. H. J. Gauvain at Alton. Already his published results of treatment form a valuable contribution to surgery. But when he forsakes the concrete for the abstract, and, to support his theory of muscular spasm, assumes the action of a whole system of muscles *which does not exist*, it is, I think, right to protest.

If you will turn to his article in your issue of March 4th, and look at page 569, left-hand column, line 21, and onwards from there to the middle of the next column, you will find the following statements: (*a*) "The degree of deformity depends on numerous factors, of which may be enumerated ..... amount of muscular spasm." (*b*) "The causes of the primary deformity are ..... (3) muscular spasm secondary to the inflammatory process." (*c*) "The next point to be most strongly emphasised ..... is the effect of the muscular spasm." (*d*) "The eroded vertebral body under the constant

strain of its investing irritated muscles is gradually compressed and at length gives way. Deformity once commenced proceeds more rapidly as the mechanical advantage under which *the anterior spinal muscles* act becomes more pronounced, while the opposition offered by the posterior muscles simultaneously decreases." (*e*) "'As soon, however, as the body bends forward, as it must at the seat of the disease, the posterior muscles, because obliged to pull round the angle of the knuckle, work at a distinct disadvantage. ..... *The anterior muscles* improperly antagonised draw the body forward.' (Quoted from Goldthwait, Painter, and Osgood.) The muscles once contracted, if left to themselves, do not relax, but remain permanently shortened. Even if the disease does become arrested they still anchor down the bent and by this time the commonly ankylosed spine. ..... In dorsal caries the baneful effects of this are particularly apparent."

Now, Sir, where are these *anterior spinal muscles?* You will admit that they exist only in the imagination of Mr. Gauvain. If Mr. Gauvain were to examine a cadaver he would find that the longus colli ceases at the third dorsal vertebra, and that the psoas magnus commences at the twelfth. Between these vertebræ there are no anterior muscles at all, yet he speaks of their "baneful effects" as particularly apparent here. Moreover, in the very regions, the cervical and lumbar, where there are muscles which could conceivably act as he describes, the angular deformity is least marked. (I need not enter into the reasons for that here.)

If Mr. Gauvain's theory—or is it Dr. Goldthwait's?—of muscular spasm as a cause of deformity in spinal caries be correct, it must surely hold good for the dorsal region, which the disease most frequently attacks, and where that deformity is most marked. But it does not hold good, for there *are* no muscles. Is it possible that Mr. Gauvain has been unconsciously led away by the plausible and voluminous output of Dr. Goldthwait, M.D.?

I am, Sir, yours faithfully,

London, March 7th, 1911. PAUL B. ROTH, F.R.C.S.

## THE TREATMENT OF MALIGNANT STRICTURE OF THE ŒSOPHAGUS, WITH ESPECIAL REFERENCE TO INTUBATION AND TO RADIUM.

*To the Editor of* THE LANCET.

SIR,—I notice in your issue of March 4th a letter from Dr. William Hill in which he is kind enough to mention my name in connexion with anæsthesia during endoscopic procedures.

Having had the privilege of being associated with Dr. Hill as anæsthetist in a great number of his cases it was with great regret that I found myself unable to be present at his demonstration before the Medical Society, and I should like to take this opportunity of corroborating and slightly amplifying his remarks as to the methods I have so far found useful in meeting the requirements of the operator during the passage not only of the gastroscope but the œsophagoscope and laryngoscope as well. Whatever method of induction may be used it is obvious that anæsthesia can only conveniently be maintained by means of the Junker bottle and tube and, as Dr. Hill says, either chloroform, C.E., or pure ether may be administered by this method according to the circumstances of the case. I early learnt from Dr. Hill that there were three important desiderata in these cases—absence of mucus, a perfectly quiet anæsthesia free from cough and retching (and this in spite of alterations in the position of the head and occasional intermissions in the administration), and, lastly, in laryngoscopic examinations a tender consideration for the examiner's eye on which chloroform vapour acts as an irritant. The secretion of mucus may best be avoided by a preliminary injection of atropine and by abstaining from the use of ethyl chloride or closed methods of ether administration during the induction; C.E. slowly administered on a mask is my usual procedure. To obtain the necessary type of anæsthesia I find a preliminary injection of scopolamine and morphine of the greatest possible service; this also generally allows of fairly long intervals in the administration of the anæsthetic, during which the examiner can explore the larynx or trachea in comfort, free from the irritation of expired chloroform vapour. For intra-laryngeal cases I use the Bellamy Gardner tube, though I think there is room for some improvement here, and should like to see a laryngoscope made with an arrangement for the delivery of the anæsthetic vapour near its lower end. When the œsophagoscope or gastroscope is being used the respiration is not infrequently embarrassed, the patients are often old and feeble, and I find a slow stream of oxygen passed through the Junker bottle of great service.

I am, Sir, yours faithfully,

Talbot-road, W., March 9th, 1911. G. A. H. BARTON.

## AUTUNITE (HYDRATED URANIUM-CALCIUM PHOSPHATE).

*To the Editor of* THE LANCET.

SIR,—Your readers may be interested by a brief account of the radio-active mineral referred to by Dr. Churchward in his article in your issue of March 11th.

Hydrated uranium-calcium phosphate, or "autunite," is a natural uranyl phosphate known for some time as existing in France (notably at Autun—whence the name) and in Cornwall, and recently proved to occur in great quantities in certain districts in Portugal. It is now worked for radium. The precise origin of the ore is debated, but it occurs largely as a crystalline deposit in tracts of decomposed granitic rock. The average mineral, as worked, contains between 1 and 2 per cent. of the uranium; but here and there are found "couches" containing clusters of uranite crystals, often of some size and of great purity. This, I take it, is the mineral used by Dr. Churchward. The pure hydrated crystal contains approximately the equivalent of 50 per cent. uranoso-uranic oxide; its theoretical "activity" is therefore patent to any student of radio-activity.

A most interesting point arises here. Certain French chemists, now engaged on the separation of radium from this ore, maintain that the available radium therein is in excess of the theoretical "radium-uranium constant" hitherto recognised. I think I am correct in stating that this has not yet been formally substantiated; but it would be interesting in this connexion to see Dr. Churchward's experiments repeated with an equal amount of, say, pitch-blende containing the same percentage of uranium as the phosphate. On the "constant" theory the activity should be approximately equivalent.

If Dr. Churchward would state the amounts required I would gladly lend any medical man interested the requisite autunite from my collection should he care to go into the matter practically. I might add that the medical use of crude radio-active mineral is not entirely new. It has been employed in France, and also, I believe, by Professor His, of the Charity Clinic in Berlin, though on different lines from those indicated by Dr. Churchward. As a layman I naturally write of these matters with diffidence, but the subject is one in which I am much interested, as I have been connected with the scientific side of this industry since it first attracted attention in this country some few years back.

I am, Sir, yours faithfully,

B. HUGH ROLFE, M.A. Oxon., C.E.

Parliament-street, S.W., March 11th, 1911.

## THE DISEASES OF MALNUTRITION.

*To the Editor of* THE LANCET.

SIR,—The agitation in favour of what is described as "standard bread" is one of those public movements which, rightly supported, are likely, both directly and indirectly, to be productive of good. Anything which has a tendency to improve the quality of the food upon which the poorer classes mainly rely for their sustenance must react beneficially upon the well-being of the community generally. The extent to which malnutrition is concerned as a primary cause of disease has probably never been fully considered nor accorded the measure of attention which its importance demands. The danger which environs everyone who has drifted into an advanced condition of "diminished resistance" cannot be disputed. The tissues are prone in such cases to become the prey of every pathogenic organism to the infection of which they may be exposed. One of the causes

of this diminished resistance is improper and insufficient food, precisely those exigencies to which, for the most part, the poor are subject. Take, for example, the case of corneal ulcers, so frequently met with among ophthalmic out-patients. In the great majority of instances this disease—practically never seen among the better classes—is unquestionably the result of nutritional defect. The cornea receives probably a small accidental abrasion of its epithelium, the repair of which in a healthy person would be generally effected in a few hours. But in those in whom diminished resistance is present no repair occurs and a corneal ulcer results, as seen so frequently among the children of the poor applying for relief at a hospital. When centrally situated these ulcers after repair are the cause of much diminution of vision, and an eye so affected is permanently damaged for visual purposes. It follows, therefore, obviously, from this, that if the staple food of the poor—namely, bread—can be rendered more nutritious by the introduction of a standard quality, the diseases of malnutrition, of which corneal ulcer is one, would become presumably less frequent in their incidence. Underlying this question there is, however, a national aspect from which it may be viewed. Corneal opacities, incurred in childhood, owing to the diminution of vision to which they give rise, become the cause of rejection of many an otherwise eligible candidate for the combatant services. Anything, therefore, which tends to improve the nutritive qualities of the food upon which the poorer classes mainly subsist must indirectly prove advantageous to the State as a whole.

I am, Sir, yours faithfully,

Wimpole-street, W., March 11th, 1911. PERCY DUNN.

## THE ETIOLOGY OF "LATE RICKETS."

*To the Editor of* THE LANCET.

SIR,—In an article which appeared in THE LANCET of Oct. 23rd, 1909, I described a case of the type to which the term "late rickets" is usually applied. The child, a girl, was perfectly healthy up to the age of 13, about which time there appeared deformities of the lower limbs and curvature of the spine. She was treated without avail for nine months, at the end of which time the family left the district. I have recently traced the case, and regret to say that the condition shows no improvement, though the child's general development corresponds with her present age (15). She has had no medical treatment since I saw her in 1909.

A case of this kind has recently been shown before the Royal Society of Medicine, when the suggestion was made that the changes in many instances of so-called late rickets are in reality allied to those found in mollities ossium. In this connexion I may perhaps be permitted to recall that I made a similar suggestion in the article above referred to, and that you were kind enough to endorse this opinion in an editorial note.

I am, Sir, yours faithfully,

Bishop Auckland, March 6th, 1911. F. HERNAMAN-JOHNSON.

## THE INTERCOMMUNICATION OF NERVES.

*To the Editor of* THE LANCET.

SIR,—In St. Thomas's Hospital Reports of the year 1874 a paper entitled "Intercommunication of Nerves" is published under my name, laying before the reader evidence in proof of three propositions—namely: 1. That structures bearing a functional relationship to one another are generally supplied by the same nerve. 2. That in regard to parts thus related, though not supplied by the same nerve, communications are often established between their respective cerebro-spinal nerves through ganglia. 3. That certain branches of the sympathetic have in their distribution a definite relation with cerebro-spinal nerves arising from the same region.

In this paper appears the hypothesis of the protective reflex and the basis of the doctrine of referred pain. Having read somewhere lately that the new views on pain, now almost universally entertained, took their origin from ideas expressed by Ross first published in the year 1888 in an article in *Brain* I hope you will give me space to draw attention to a prior claim of originality for these views.

I am, Sir, yours faithfully,

Streatham-hill, S.W., February, 1911. H. WALTER VERDON.

## EYE-STRAIN IN RELATION TO GENERAL HEALTH.

*To the Editor of* THE LANCET.

SIR,—Mr. A. A. Bradburne, in his letter to this week's LANCET, avers that: "Brain-fag arises from congestion of the high visual centres owing to the difficulty of interpreting 'slightly fogged' pictures and unequal visual representations, and leads to anæmia of other centres and the various organs which demand a good blood-supply." Admitting the ingenuity of the argument, it is very doubtful, however, if the cerebral circulation is under the influence of the vaso-motor system. Leonard Hill persistently failed to get any vaso-motor effects by stimulating the sympathetic nerves supplying the brain, and Bayliss holds that the cerebral vessels are devoid of vaso-motor control. But, assuming the local-anæmia-cum-congestion hypothesis of Mr. Bradburne to be correct, how can it explain "eye-strain" in view of the fact that the brain itself is insensitive!

I am, Sir, yours faithfully,

London, March 11th, 1911. KENNETH CAMPBELL.

## A CORRECTION.

*To the Editor of* THE LANCET.

SIR,—In your report in THE LANCET of March 11th of the pathological specimens shown at the Medical Society of London on Feb. 27th, the account of my case of Cyst of the Upper Extremity of the Femur has been so curtailed as to omit the most important fact—viz., that the cystic portion of the femur was resected. It was only after this had been done that the head of the femur appeared to be too small to serve any useful purpose and was resected, allowing the upper end of the shaft to be secured in the acetabulum. From your account it would appear as if the only treatment had been resection of the head of the femur. The portion of bone involved in the cyst was shown at the meeting.

I am, Sir, yours faithfully,

P. MAYNARD HEATH.

Weymouth-street, W., March 13th, 1911.

## LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

*New Maternity Hospital for Liverpool.*

THE committee of the Maternity Hospital and Ladies' Charity has secured an admirable site for the proposed new hospital by the purchase of the old almshouses in Cambridge-street. By means of the sale of the present maternity hospital in Brownlow-hill, the committee will be enabled to pay for the site of the almshouses and other incidental expenses. The surplus, if any, will be devoted to an endowment fund of £20,000, which Sir William Hartley made a condition antecedent to the erection, at his personal cost of not less than £15,000, of a new hospital capable of meeting the demands of the charity. Towards the £20,000 endowment, over £10,000 have already been raised, and as soon as £5000 more are forthcoming building operations will be commenced. The site has had the approval of Sir William Hartley, and if it had not been promptly secured the lands would have passed into other hands as a site for carriage works. Situated midway between the University of Liverpool and the Infirmary for Children, the old almshouses for widows will appropriately give place to a hospital for women and a training school for nurses and midwives. The almshouses were erected in 1789, while the Ladies' Charity was founded in 1796, its first maternity hospital being erected in 1841. In 1869 the charity was amalgamated with a kindred institution, so that it has been continued for upwards of 40 years on the present basis, and for 115 years since the foundation. The need for a new maternity hospital is pressing. Within the boundaries of Liverpool 23,600 children were born in 1910. The maternity hospital, with its 23 beds, was the only provision outside the workhouses for all the cases from the poorer classes presenting difficulties. Over 100 cases, after having been deemed suitable for admission, were refused for lack of room—a fact amply demonstrating the need for larger accommodation.

*Mr. F. W. Lowndes and the Liverpool Police.*

Mr. F. W. Lowndes has resigned his post as medical officer of the Liverpool police force after a distinguished career of 34 years, and will terminate his duties in connexion therewith on June 30th. Mr. Lowndes has always been recognised as a man brimming with public spirit. By his persistent advocacy of a united effort to further and to assist the monetary condition of the local charities, now 40 years ago, Liverpool is mainly indebted to him for its early foundation of the Hospital Sunday collections. He was also the first to suggest the establishment in Liverpool of an annual medical service on St. Luke's day, an institution which has now become very popular, and which has been ministered to by some of the best-known preachers of the day. During a long and useful career at the Liverpool Lock Hospital, with its 50 beds (now a special department of the Royal Infirmary), he was always in the van of any movement for the betterment of the female patients, and he greatly interested himself in promoting their welfare on their discharge. He contended almost single-handed in this worthy cause. The closing of the hospital, in so far as the in-patients were concerned, was a great grief to him, as none knew better than he the value, physically and morally, of such an institution. He was greatly interested in toxicology, and figured in many sensational criminal cases, notably at the trial of Flanagan and Higgins, the sordid child poisoners, who were convicted and hanged in 1884; and was also a telling medical witness at the trial of John Conway, who was hanged for the brutal and mysterious murder of a young lad. Mr. Lowndes was instrumental in securing an up-to-date mortuary at the Prince's Dock, and also interested himself in gaining better accommodation for medical witnesses at the assizes. He was, if not the first, one of the earliest pioneers in advocating the abolition of the dirty practice of "kissing the book" in courts of law.

*The Liverpool Medical Institution.*

The council of the aforesaid society, with the sanction of the trustees, unanimously decided to propose a change of name from "The Liverpool Medical Institution" to that of "The Medical Society of Liverpool," to the members at the annual meeting held on Jan. 12th. The proposition of the council was then carried by more than the requisite majority. An agitation shortly afterwards sprang up in favour of reverting to the old name, and, after a discussion at a special meeting called for the purpose, a reversal of the decision arrived at in January took place.

March 14th.

## NEWCASTLE-ON-TYNE.

(FROM OUR OWN CORRESPONDENT.)

*Royal Victoria Infirmary, Newcastle-on-Tyne: Annual Court of Governors.*

ON Saturday, Feb. 25th, the annual court of governors was held in the out-patient hall of the infirmary, the Lord Mayor (Sir William Stephenson) presiding. There was a very large attendance of governors, including Sir George Hare Philipson, Sir Thomas Oliver, and Sir Riley Lord. The Lord Mayor moved the adoption of the reports, commenting on the fact that the income had not come up to the expenditure, though the deficiency was less than that of last year. The workmen's subscriptions showed an advance during the year of £784—excellent considering the labour difficulties, stoppages, and inconveniences, and this was very hopeful. His lordship then referred in a brief way to the chapel dispute, which he hoped might now be in a fair way of being settled. Sir George Philipson seconded the motion, which was adopted. Mr. William Sutton then presented the financial statement for adoption. The total income had been £33,559, as compared with £31,242 of last year. The total expenditure had amounted to £36,593, as compared with £35,540 of last year. The deficit on the year's working amounted to £3034, that in 1909 to £4297, showing a reduction of £1263. He hoped they had begun a successful movement in this matter and that their income and expenditure might be more equal. He referred in terms of satisfaction to the gift of £1000 from the Newcastle Coöperative Society to endow two cots in celebration of its jubilee. Referring to the workmen's subscriptions, he said they amounted in 1901 to £5000, while last year they were £17,000. The number of out-patients in 1906 was 50,000, and now in 1910 it had reached 90,000. Mr. Blake, in seconding the adoption of the financial statement, wished to urge upon the governors that the committee was not in any way extravagant, and he said that taking the whole of the people with whom they had to deal the expenditure per patient per day is less than 2*s.* 10*d.* The expenditure on sisters and nurses was higher than in other places because there were fewer patients per nurse. Moreover, in the feeding arrangements only the very best possible food was supplied. The report was adopted. Sir Riley Lord then presented the report of the subscriptions committee and gave some interesting figures showing how meagrely certain districts, from which large numbers of patients were sent, supported the infirmary. He controverted the impression that the institution should be solely supported by the working-classes, saying that the wealthy classes benefited quite as much from the infirmary as the working classes, for the former had the benefit of surgeons who had gained wide experience, knowledge, and skill from infirmary practice. With regard to subscriptions, he regretted to say that there were many serious deficiencies from some places as between the amount subscribed and the number of patients sent in. In some of the large works the deficiency was as much as £300. Twenty-four collieries round the city of Durham sent patients costing the institution £422 more than was subscribed. Twelve of those collieries did not subscribe a penny and the rest subscribed something. Other instances were given as to this failure to subscribe. The report was seconded and adopted. The house committee and selection committee for the ensuing year were then elected.

As to the above account of the proceedings at the Royal Infirmary governors' annual meeting, the dominant feature of the report seems to be the increased support given by the workmen to the institution, the amount being collected in an organised way over the whole of Tyneside and the various colliery parts of Durham and Northumberland. It will be seen that thus subscribed in a coöperative fashion the income from this source is more than half the total income of the institution. So far so good, there could be no complaint of such organised measures. The consideration of the remarks falling from the mover of the adoption of the report of the subscriptions committee compels one to wonder what the end is to be. He manifested complaint that there was some lack of response on the part of collieries and their workmen, having regard to the fact that some of the latter had been treated in the institution, and instances of this were given. To ask for the subscriptions of a colliery because some of its workmen have been treated in a charitable institution, and to urge a continuance of subscriptions collected by means of small weekly donations of 1*d.* or 2*d.*, carries with it the almost inevitable corollary that a subscription given means the right to free treatment. There is a positive danger that the whole object of the infirmary as a charitable institution may be lost sight of, and, indeed, examples of this are not infrequently met with in this district; for instance, remarks are constantly made to practitioners who have lost patients: "I took the child to the infirmary; my husband pays to it!" While there are undoubted advantages to be gained mutually both for the house committee and for the workmen from the large subscriptions collected for the infirmary, there is a source of danger underlying the system, which may perhaps only be realised when it is too late, and thus the whole character of the institution may be altered.

*Barrasford Sanatorium.*

On March 7th the annual meeting of the Newcastle-on-Tyne and Northumberland Sanatorium was held in the Royal Infirmary, under the presidency of Lord Armstrong. The committee were able to produce a favourable report from several points of view. The number of patients treated during the previous year was 163, while some 62 were rejected as unsuitable for such treatment. Financially the sanatorium appears to be satisfactory, since the committee can report a reduction of a £3000 deficit in 1907 to now about £230. The income for last year was £4367 15*s.* 9*d.*, and the expenditure £4134 8*s.* 5*d.*, leaving a balance of some £233 to be carried to the capital account. "The committee feel that the institution has by now proved its necessity in

the county, and would therefore justify the support of Northumbrians in aiding them to do a work which can be regarded as of the first importance in raising the standard of health, and endeavouring to stamp out a disease which cuts down so many young and promising lives."

March 13th.

## BRISTOL AND THE WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

### *Bristol General Hospital.*

THE Lord Mayor of Bristol presided at the half-yearly meeting of this institution on March 13th, and was supported by the Bishop of Bristol and the High Sheriff. The annual report showed a more satisfactory state of affairs than in 1910. The in-patients showed a decrease of 49 (2651 as against 2700), due to the fact that the accommodation for in-patients is at present taxed to the utmost; the out-patients were 40,043, the largest number yet recorded. The average stay in hospital was 24·8 days, and the proportion of beds in average daily occupation was 90 per cent. The dental department, working in temporary premises, had dealt with 4891 patients, but at such inconvenience that some better accommodation is urgently necessary. The ordinary income, £12,071, is the largest since 1904; the ordinary expenditure amounted to £14,757, an excess of £2686 over income. The balance due to the treasurer has, however, been reduced to £2216; and workpeople's contributions amount to £2335. An important expansion of the hospital premises is to be made to accommodate a lying-in ward and ampler provision for other female patients, together with certain other necessary departments. The estimated cost is £45,000, and the Lord Mayor has promised to preside over a meeting at the Guildhall for the purpose of raising the money. Some generous contributions have already been received, including one of £5000 from Mr. Henry Overton Wills, Chancellor of the University. A pleasant feature of the meeting was the kindliness of the allusions to the work of the staff and students. The general hospital committee is clearly fully alive to the wider responsibilities of a hospital in regard to teaching and research.

### *Antivivisectionists in Bristol.*

The National Antivivisection Society, which has recently opened a shop in Clifton for the dissemination of its literature, held a meeting last week at the Victoria Rooms, at which Mr. Stephen Coleridge was advertised to speak on the Research Defence Society. Mr. Stephen Paget asked to be allowed to speak from the platform on equal terms. In consequence of this request, with which the Antivivisection Society complied, the large hall was well filled. After introductory remarks by the chairman, Canon Talbot, Mr. Coleridge spoke for 10 or 15 minutes, chiefly criticising cancer research. Mr. Paget's 20 minutes were occupied with an account of the Research Defence Society, its purposes, and the number of its membership, while he added an effective summary of the extent to which vivisection is in daily use on behalf of the national health and with the sanction of the nation through its representatives in Parliament and other governing bodies. He defended the use of animal experiments in cancer research, agreed with Mr. Coleridge as to the need of more inspection, and concluded by entreating the "man in the street" to ask his own doctor what he thought of vivisection. Various questions were put, to which both Mr. Coleridge and Mr. Paget replied, and each spoke for ten minutes in conclusion, Mr. Coleridge having the last word. No vote was taken; but so far as the cause of scientific research is concerned, it is to be hoped that Mr. Paget will find Mr. Coleridge's platform open to him in other places.

### *Royal Hospital for Children and Women, Bristol.*

At the annual meeting of the supporters of the Children's Hospital, Bristol, the secretary's report included various items of interest. First, he said that Their Majesties the King and Queen had extended their patronage to the hospital, in succession to King Edward VII., who had been its patron. The year's work consisted of the treatment of 767 new in-patients and 5408 new out-patients. The financial position is fairly good; the income was £4808 14*s.* 10*d.* and the expenditure £5128 3*s.* 4*d.*, leaving a balance due to the treasurers of £319 8*s.* 6*d.*, as against £155 13*s.* 2*d.* last year. Subscriptions and donations amounted to £1540 17*s.* 3*d.* The fund to provide a new out-patient department had increased during the year by over £200. The legacy account showed a balance at the bank of £381 2*s.* 10*d.* The Sheriff of Bristol, Mr. George Riseley, who took the chair, urged the necessity of coördinating the hospital work of Bristol owing to the wastefulness of the present competition and want of system which are apparent to unprejudiced laymen as well as to members of the medical profession. Mr. Riseley said it was a pity the existing hospitals had gone so far in their separate careers that it was too late to think of concentrating all their work in a single building. These remarks were warmly supported by Dr. Bertram Rogers, senior physician to the Children's Hospital, who said that its position at the top of a steep hill made it almost inaccessible for cases of acute illness. A letter of congratulation from Queen Alexandra to Miss Parry of Alveston, who has done a great deal for the hospital in securing financial support, was also read.

### *Poor Milk.*

At Bristol police-court recently the National Dairy Company was summoned in respect of two samples of milk, one being deficient in milk fat to the extent of 17·33 per cent., and the other containing 43·53 per cent. of added water. The magistrates inflicted a fine of £20 in each case and 5 guineas costs.

### *The Plymouth King Edward VII. Memorial Fund.*

At a meeting recently held in Plymouth in connexion with the memorial to the late King it was decided to erect, at a cost not exceeding £500, a suitable wing at the Didworthy Sanatorium, to accommodate six beds, to be used for patients from Plymouth, and to be named the "King Edward VII. Pavilion." It was further determined that the remainder of the money subscribed should be vested in trustees for the support of a "consumption dispensary" in Plymouth.

### *A Plymouth Research Defence Society.*

It was decided at a meeting last week to form a Plymouth, West Devon, and Cornwall branch of the Research Defence Society. Mr. W. Paul Swain was elected president and the Rev. Dr. Trelawny-Ross, Admiral Marrach, and Colonel M. Giles vice-presidents, and Mr. R. Jaques honorary secretary.

### *The Health of Taunton.*

Dr. H. J. Alford, the medical officer of health of the urban and rural districts of Taunton, in his annual report for 1910, states that the death-rate in the urban districts was 12·6 per 1000, the corrected death-rate being only 11·7 per 1000, the lowest recorded. Six deaths were due to zymotic diseases, compared with an average of 18 for the past 10 years. The birth-rate was 21 per 1000. The infantile mortality was 76·2 per 1000 births. This decreasing rate Dr. Alford believes to be due to the Notification of Births Act and the appointment of a health visitor. In the rural districts the death-rate was 14·3 per 1000, the corrected death-rate being 11·2 per 1000. Seven deaths were due to zymotic diseases. The birth-rate was 20 per 1000. The infantile mortality was 46·3 per 1000 births.

### *The Health of Lynton (Devon).*

Dr. H. J. Edwards, the medical officer of health of Lynton, in his annual report for 1910 states that 19 deaths occurred, equal to a rate of 10·76 per 1000. Of this number one was over 90, two were more than 80, six were above 70, which certainly speaks well for the health of the district. Only one of the deaths occurred in an infant under 1 year. The birth-rate was 19·26 per 1000. Only one infectious disease was notified, and that in a visitor who arrived in the initial stage of enteric fever. Dr. Edwards states that the rainfall was unusually heavy during 1910—viz., 54·16 inches, as compared with 41·95 in 1909, and 38 inches, the average for the past 35 years.

### *"Loose and Shadowy Assertions."*

At the Frome (Somerset) county court on March 7th, before his honour Judge Gwynne-James, Dr. A. Sykes-Ward sued a man for 10 guineas for medical attendance. For the defence it was contended that some of the visits for which plaintiff claimed had not been made, and that there had been a lack of skill in his treatment of the case. His honour, in giving judgment for Dr. Sykes-Ward, said there was not a tittle of evidence that the visits charged for had not been made and that the treatment was not of the best.

March 14th.

# SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

*Question of Precedence between the Royal Colleges.*

FOR some years past the Royal College of Surgeons of Edinburgh has questioned the right of the Royal College of Physicians of Edinburgh to take precedence at public functions. In 1901 Lord Balfour of Burleigh, then Secretary for Scotland, accorded to the Royal College of Physicians precedence on the occasion of the presentation of addresses to His late Majesty King Edward VII., and intimated to the Royal College of Surgeons that this decision would be acted on by the Scottish Office until disturbed by any higher authority. Recently the Royal College of Surgeons presented a petition to the Lyon King of Arms, claiming on various grounds that it is on all public and ceremonial occasions entitled to precedence over the Royal College of Physicians, or otherwise that such precedence should be granted it. The petitioners submit, with reference to the decision of 1901, that no power to deal with such matters has been committed to, or is possessed by, the Secretary for Scotland, and that the decision, which was given on representations by the Royal College of Physicians without any opportunity being given to the petitioners for being heard thereanent, and which subverted the existing usage, was beyond the jurisdiction of Lord Balfour, and is wholly inept and ineffectual in law. Answers to this petition were lodged by the Royal College of Physicians and Dr. Byrom Bramwell, the President, stating that on Feb. 9th, 1911, they presented a petition to His Majesty the King on the matter, and submitting that the present proceedings before the court of the Lyon King ought to be sisted *in hoc statu* to await the declaration of the King's pleasure on the petition of the respondents. The respondents maintain that the petitioners have no right to precedence over them by usage or by any other title. On March 3rd the Lyon King of Arms intimated that he had fixed Thursday the 9th for the purpose of hearing parties as to further procedure. On March 8th the petitioners were informed by the Lyon King that he had received a letter from the Secretary for Scotland, who stated that after consultation with the Lord Advocate he was of opinion that the Lyon King had no jurisdiction in the matter, and that the proper course was for him to decline to jurisdiction. He therefore would issue an interlocutor in terms of the instructions he had received. Following this communication the Royal College of Surgeons, through its agent, intimated its desire to protest in the strongest possible way against the issuing by the Lyon King of an interlocutor in terms of the instructions of the Secretary of State for Scotland, stating that the College did not consider it within the province of either the Secretary of State for Scotland or the Lord Advocate to interfere with one of the courts of the realm in the discharge of its functions, and intimating that it would at once appeal against the interlocutor which the Lyon King had intimated that he was about to issue. The interlocutor was issued on March 9th, and the Royal College of Surgeons appealed against it.

*Death of Dr. Andrew Smart.*

The death occurred on March 8th of Dr. Andrew Smart at his son's house in Hendon, in his 87th year.

*Aberdeen Dispensary: Serious Financial Situation.*

The annual meeting of the supporters of the Aberdeen Dispensary, Maternity Hospital, and Vaccine Institution was held in the Town Hall, Aberdeen, on March 7th. In the annual report the committee makes a special appeal for support, calling attention to the growing seriousness of the position now occupied by the Dispensary and Maternity Hospital in consequence of the increasing debt. Unless successful efforts are speedily made to relieve the pressure upon the finances the operations of these institutions, which have hitherto been worked under one board, will have to be either contracted or suspended altogether. The committee appeals most earnestly for adequate funds to carry on the work. The committee of management has under consideration the preparation of a scheme for the separation of the dispensary from the Maternity Hospital and the creation of a new board for the management of the latter institution. In this way it is hoped that the future financial position, both of the dispensary and of the hospital, may be put on a more satisfactory basis. A motion to adjourn the meeting for a month was unanimously agreed to. In the meantime a committee has been appointed to inquire into the financial position and confer with the medical staff and other parties interested to ascertain whether it is possible to continue the institutions and on what conditions.

*Tuberculosis and Occupation in Aberdeen.*

Dr. Matthew Hay, medical officer of health of Aberdeen, in his report on tuberculosis, gives statistics regarding occupation and tuberculosis in Aberdeen. He finds that the percentage of deaths from phthisis to deaths from all causes is highest for printers and lithographers (33 per cent.), stonecutters and masons (31 per cent.), and clerks (26 per cent.). These are considerably above the rest. The percentage is lowest for bakers, carters, joiners, and labourers, with from 7 to 9 per cent. In a table giving the death-rates from phthisis and other causes per 1000 persons employed in the selected occupations, and for comparison the corresponding death-rate among the whole population of the city at ages above 21 years (males and females being separately distinguished), it is shown that stonecutters and masons stand above all others with a death-rate 5·7 per 1000 from phthisis—that is, three times as high as the average rate, 1·9, for males above 21 years. If allowance be made for the inclusion of wallers, among whom the mortality from phthisis can scarcely be greater than the average, the death-rate of persons actually engaged in the cutting and hewing of granite is probably 6 2 per 1000. Next to stonecutters come printers and lithographers with 4·5 per 1000. Then combmakers with 4·3, clerks with 3·8, and tailors with 3·2 per 1000. Such are the occupations of those investigated in Aberdeen that may be said to suffer unduly from phthisis. The fact is noted that dressmakers and milliners do not suffer to the same extent as tailors and clerks from phthisis, and Dr. Hay suggests that the somewhat larger amount of physical exercise may in part account for this, although it does not seem to have the same effect on tailors; also, in the death registration, the occupation may not, especially in the case of younger women, be always stated. Carters and engineers (including blacksmiths and similar workers in iron) are the healthiest of occupations for males dealt with. Attention is drawn to the exceptionally large number of deaths among stonecutters after 55 years of age. In nearly every other occupation except labourers phthisis is relatively rare as a cause of death after that age, and it is possible that in Aberdeen at any rate the large average among labourers is due to the presence among them of former stonecutters. From careful comparing of statistics it seems to be proved that the use of pneumatically driven tools, which produce more fine dust than the chisel, has prevented stonecutters and masons from sharing in the general decline of the death-rate from lung diseases. Dr. Hay says that use of closed sheds in place of the old open ones may account for the diminution of diseases of the lung other than phthisis in these occupations during the last five years, for while the closed shed increases the liability to inhale dust it affords some protection against cold. Dr. Hay suggests that entrance to trades with a high mortality from phthisis should be guarded, as far as possible, from youths with a definite family history of tuberculosis or with defective chest development or lung weakness.

*Victoria Hospital, Dundee.*

The annual meeting of the supporters of the Victoria Hospital, Dundee (formerly the Incurable Hospital), took place on March 10th. Dr. Martin Whyte, in seconding the adoption of the report, said that some cases which had been admitted as incurable had been cured. He wished that the question of treating advanced cases of phthisis could be faced. Many schemes were proposed for a King Edward memorial, but he did not think they could do better than follow the example of Glasgow. Dr. Alexander Campbell said that at the Victoria Hospital they took in advanced cases of phthisis. Dr. C. Templeman stated that the local authority recognised that it was its duty to deal with advanced cases of phthisis which were a serious danger. The report was adopted.

March 13th.

# IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

*Poor-law Guardians and Private Practice.*

POOR-LAW guardians in Ireland in many instances attempt to interfere in the private practice of thei medical officers, and not infrequently even demand an explanation from a medical officer of some matter occurring in his private practice. The Local Government Board, curiously enough, has not discouraged this proceeding, and has even suggested that boards of guardians might with advantage attempt to arrange scales of fees to control the medical officers in their charges. This proposal has often been made, both by the Local Government Board and by local boards, in answer to the just complaint of the medical officers that many people, other than "poor persons," claim and obtain the benefit of free medical attendance. It is said that if people of moderate means could be sure of obtaining attendance for a moderate fee they would be willing to pay it, whereas at present they claim free attendance. The medical profession, however, while expressing willingness to see patients of moderate means for moderate fees, has steadfastly refused to recognise the right of boards of guardians to put pressure upon them. A determined effort is now being made in the Swinford district in county Mayo to coerce the medical profession. A vacancy having occurred in the post of dispensary medical officer a meeting was held of the local clergy and guardians. At this meeting a scale of fees was drawn up which the guardians proposed should be binding on the prospective medical officer. According to this scale, the medical officer was to afford advice, attendance, and medicine to all classes at certain fixed rates. It was proposed to insert the scale in the advertisement of the approaching election, and acceptance of the scale was to be a condition prior to appointment. The Local Government Board has, of course, had to point out that the insertion of such a condition in the appointment would be *ultra vires*. The local board, however, remains obdurate, and has decided not to make any appointment unless its wishes can be carried into effect.

*King's Professor of Midwifery, Trinity College.*

Mr. Thomas H. Wilson has been elected King's Professor of Midwifery in the School of Physic in succession to Dr. Henry Jellett, who resigned on being appointed Master of the Rotunda Hospital. Mr. Wilson has been gynæcologist to the Richmond Hospital for many years, and was acting professor of midwifery for a year after the death of Sir Arthur Macan. He is, therefore, a teacher of experience.

*National Maternity Hospital, Dublin.*

The report read at the annual meeting of the National Maternity Hospital last week showed that the number of intern patients during the year amounted to 898, whilst those attended at their own homes by nurses and medical men numbered 1135. There had been over 4000 attendances during the past year at the dispensary. The total income for the year amounted to £3650 5*s*. 11*d*., and the total expenditure to £3665 5*s*. 7*d*., leaving still an overdraft of over £4000. The hospital receives a grant of £250 a year from the Dublin corporation.

March 14th.

# PARIS.

(FROM OUR OWN CORRESPONDENT.)

*Personal Attendance of Pharmaceutical Chemists at their Dispensaries.*

LEGAL action has recently been taken in a case in which a pharmaceutical establishment was for the most part in charge of a man having only the status of a *préparateur en pharmacie*, the qualified principal being in attendance only from 5 to 7 P.M. Both of them were prosecuted in a court of justice, the former for the illegal practice of pharmacy and the latter as an accomplice in this offence. Counsel for the defence argued that all the prescriptions were dispensed in the evening under the supervision of the principal, and that during the early part of the day the assistant sold no medicines, but only such things as mineral waters and tooth-pastes. In the result the court fined the assistant 500 francs with time for payment, and fined the qualified principal 500 francs, to be paid forthwith.

*An Exhibition of Artistic Productions by Medical Men.*

A Salon Médical, or exhibition of the works of artists belonging to the medical profession, has been formed in Paris at No. 31, Boulevard des Italiens, and will continue from March 28th to April 5th. This exhibition, which has received the distinctive name of Salon des Asclépiades, will be open from 9 A.M. to 6 P.M. It will contain examples of painting, sculpture, pastel, engraving, and decorative art, whether previously exhibited or not, by medical men, *internes*, and medical students. In addition to the above-mentioned class of exhibits there will be a section reserved exclusively for medals and artistic objects having a connexion with medicine.

*Election of a Member of the Academy of Medicine.*

At the election of a member of the Academy of Medicine in the Section of Anatomy and Physiology 60 votes out of a total of 69 were given for M. Prenant, a professor in the Faculty of Medicine.

*Immigrants from Infected Districts and the Protection of the Public Health.*

The President of the Council and the Minister of the Interior have recently appointed a commission for the purpose of considering what measures might be taken for the protection of the public health in connexion with the admission of immigrants into France, regard being had to the conditions under which the immigrants travelled and also to their residence in towns. At a meeting of this committee a communication was received from M. Mirman, *directeur de l'Assistance et de l'Hygiène Publique*, who inqnired whether in consequence of information supplied by the Minister of Foreign Affairs or in consequence of scientific progress the commission recommended any alterations of the existing method of dealing with these questions. In reply the commission recommended the continuance of the existing system, adding that there was not in its opinion any reason at present for taking special measures with respect to persons or goods coming from Manchuria or from Astrakhan, because in accordance with the general and permanent regulations of the maritime sanitary police all vessels arriving from countries infected with plague underwent careful sanitary inspection and were cleared of rats before discharge of the cargo. At the same time, it was necessary to watch the progress of the epidemic in these countries and to keep in mind that fresh developments might necessitate additional regulations.

# VIENNA.

(FROM OUR OWN CORRESPONDENT.)

*Number and Distribution of Medical Practitioners in Austria.*

THE official figures dealing with the distribution of medical practitioners in this country are now published, and they afford a remarkable insight into the prevailing conditions. At the end of the year 1910 there were altogether 13,202 licensed practitioners, as compared with 12,426 in 1905. These figures include those members of the Army Medical Corps who have also at the time in question been carrying on practice outside their official duties, the military surgeon being in some places the only practitioner for miles and miles. The number of medical men has thus increased by over 6 per cent. in five years, and since 1887 the increase is 76 per cent., whilst the population has increased by only 28 per cent. The increase of medical students was also most remarkable. Whilst in 1880 the proportion of all matriculated students in the universities who took up medicine was 13 per cent., in 1891 the proportion was 42 per cent. of all students. Now the annual mortality amongst medical men in this country is 1·8 per cent., whilst the annual increase of the population is 1 per cent. In the period from 1885 to 1904 there were 12,300 graduations of students, whilst the number of practitioners increased by 4500. This shows that either a large number of those who obtained the diploma had to give up practising in this country, or else that the number of deaths of members of the profession has been far in excess of what

was to be expected, both facts indicating the existence of unsatisfactory conditions. The increase of the profession, against which many warnings have been issued, has had the result that on an average there is now one medical man for every 2175 of the population, whilst in 1887 the proportion was one medical man for 3242. The highest percentage of increase of medical men was in Vienna, where their number was 1377 in 1887 and 3046 in 1910. Similar conditions obtain for all the larger towns, which show an enormous increase of medical men, whilst the country districts become less and less popular with the profession, as is shown by the relative decrease of their numbers in comparison with the increase of population. The over-production of medical men tends to swell the number of practitioners in towns, where they prefer to turn their abilities to specialist branches. The number of specialists in the whole of Austria has not yet been published, but only the figures for the three largest cities. From these figures it appears that there are 475 specialists in Vienna, 71 in Graz, and 200 in Prague; in 1905 there were 361 specialists in Vienna and 52 in Graz. Thus 16 per cent. of all practitioners in Vienna, 25 per cent. in Graz, and 23 per cent. in Prague are specialists. As regards the health resorts, Karlsbad heads the list with 763 practitioners, Meran has 76, Marienbad has 69, Baden has 53, Franzensbad has 50, Bozen has 37, and Abbazia has 36. These few places show an increase of 17 per cent. within the last five years. The proportion of medical men to population varies. It is only 1 per 390 inhabitants in Olmütz, which is the worst figure, but the larger cities show comparatively better conditions than the smaller towns, the proportions being 1 to 670 inhabitants in Vienna, 1 to 590 inhabitants in Prague, and 1 to 1010 inhabitants in Trieste. As regards the territorial distribution in the country, the worst condition as regards the financial outlook prevails in Galicia, where 10,000 inhabitants can only support one practitioner, whilst in Lower Austria there is one practitioner for each 2080 inhabitants. There are 80 female practitioners, or 6 per 1000 of the total. In 1903 only nine were practising. Of these 80 ladies, 39 are in Vienna, and, as a rule, they have taken up the treatment of diseases of women and children. Nearly 60 per cent. of all practitioners hold appointments in the service of either the State or the district boards of health, or with the Krankencassa (contract practice). In the country districts 80 appointments have been vacant for more than two years, because the payment offered is not sufficient to attract applicants. The necessity of organisation in order to obtain better remuneration for professional services is at last becoming understood by 70 per cent. of the practitioners in Vienna, and also by a large proportion of those who have settled in the country districts. These are the only conditions which hold out a promise for the future of our profession in Austria.

*The Austrian Cancer Research Society.*

The Austrian Cancer Research Society was inaugurated a few days ago with elaborate ceremonial in the splendid hall of the University in the presence of many scientific and social celebrities and State functionaries. The president-elect, Professor von Eiselsberg, opened the meeting, and in a most instructive speech explained the aims of the new society. He said that there were already 600 members, who would strengthen the position of those by whom the research work would be conducted. He further remarked that two leading points must be kept in mind in these investigations—namely, the etiological factor of cancer and the therapeutic use of a serum. It was also in contemplation to found an asylum for cancer patients like the one in Heidelberg, where the sufferers could be treated with a faint hope of help. Professor Fränkel, the secretary of the society, delivered a lecture on the Problems of Cancer, in which he pointed out that biological and biochemical research was at present the chief means available for solving this important mystery. He said that the group of conditions termed "disposition" had at last been reduced to a simpler form by the discovery of Freund, who ascertained that the serum of healthy persons destroyed cancer cells, whilst that of cancerous persons left these cells intact. Continued research would be accepted from all sources.

*Syphilitic Osteitis of Infants.*

At a recent meeting of the Gesellschaft der Aerzte Dr. Goldreich showed an infant, three months old, who presented a remarkable appearance of the fingers. The first phalanx of each finger, as well as that of the second and third toe on each foot, were thick and very much broader than normal, imparting to the fingers and toes the appearance of bottle-shaped disfigurations. The child had a maculo-papulous exanthem on the trunk and also specific rhinitis; no medical treatment of any kind had been given. Examination by the X rays revealed the presence of a rarefying osteitis with secondary hypertrophic periostitis of the affected bones. The metacarpal and metatarsal bones showed similar changes, but these were not visible with the naked eye or palpable. Dr. Goldreich said that this condition, which was confined to the osseous structures, the soft parts not being affected at all, was very rare. Hochsinger has collected 65 cases of affections of the fingers alone and 12 cases where the toes were also the seat of disease. Under specific treatment there was generally very satisfactory improvement.

March 11th.

## CONSTANTINOPLE.

**(FROM OUR OWN CORRESPONDENT.)**

*Cholera in Smyrna.*

FROM Smyrna comes the news that two cases of cholera occurred there with fatal results on Wednesday last. Bacteriological examination proved that they were genuine cases of cholera Asiatica. The sanitary commission of Constantinople held an extraordinary meeting at which it was decided to submit to a strict medical examination and quarantine all the passengers coming from Smyrna. Some apprehension is felt in the Turkish metropolis.

*The New Austrian Hospital.*

The Austro-Hungarian ambassador announced to a gathering at an official reception that the new Austrian hospital will probably be opened at the end of next month. It is being constructed and equipped according to the most recent requirements of medicine and surgery. It is situated on a lofty plateau near the barracks of Tashkishla, not far from Taxim, a district beyond Pera, and commands a magnificent view of the Bosphorus. It is asserted, it seems with substantial reasons, that it will be the most modern and most efficiently equipped of all the numerous hospitals of Constantinople. The construction alone will cost, when completed, about half a million kronen (£20,833).

*The Civil Medical Faculty.*

This year, says a local newspaper, only six medical students were registered at the civil medical faculty of Constantinople. This small number is very striking, as in each of the previous years the number of entering students from different parts of the Ottoman Empire amounted to between 50 and 60. Two reasons are assigned for such a decline in the numbers. First, the qualified medical men, who are sent by the Government to the provinces, receive a very small salary. In some cases when employed in municipal service they get only 600 piastres a month and must not engage in private practice. The second reason is that the medical faculty, being at Haidar Pasha on the Asiatic coast, is too far from the centre of the city. The majority of students living in Stamboul must travel backwards and forwards on the local steamers, which is rather a costly business. There are few countries which need more urgently skilful civil medical men than Turkey, especially at the present juncture, when the whole empire seems to be awakening to its possibilities in every direction. In consequence of the distance the cliniques at Haidar Pasha are also attended by very small numbers of patients. All these facts have been taken into consideration by competent authorities under the presidency of the Minister of Public Instruction. After a long discussion it has been decided, by 26 votes against 2, to transfer the cliniques to Stamboul. The question of transferring the whole medical faculty from Haidar Pasha to Stamboul is also being seriously discussed at present.

*Extraordinarily Inclement Weather.*

From all parts of Turkey alarming news reaches the metropolis of an exceedingly severe winter. Old people say that they have not witnessed such extraordinarily inclement weather for the last 40 years. Everywhere snow is falling in great abundance, the thermometer showing for many weeks

20, and in some places even more than 30, degrees below zero. Snowstorms are raging and communications are interrupted. In the province of Erzerum the calamity of an earthquake has been added to the inclemency of the weather. At Jerusalem the snow attained the depth of about half a metre, which is quite unprecedented for that part of the country. In many places the snow tempests have caused great destruction of property and loss of human lives. Whole companies of men have been found frozen to death in the vilayet of Castamouni. The need and misery of the poorer population are appalling. Many sailing vessels went down in the Marmora and Black Sea. Also at Constantinople the winter has been persistently severe for about a month. Some days the thermometer showed 6° Celsius below zero, which is quite unusual for the Turkish metropolis. As I write these lines the weather seems to be changing and a milder temperature exists.

*Terrible News of the Plague.*

From Harbin *viâ* St. Petersburg comes really terrible news of the pneumonic plague as it rages in the Manchurian town of Fu-Chia-Tien. Human activity in this place seems to have completely died out; the streets are empty and deserted and all the houses are left desolate. Those who were not struck by the plague in the town itself fled terror-stricken and were overtaken by the black epidemic outside the town. The bazaars and markets are closed. Dogs alone roam in the streets, howling and feeding on the corpses of their former masters. The stench is horrible. The hospitals are abandoned. There are no ill people any more and no medical men—all have died. Only on a few beds lie the dead bodies of those who expired last. The only living human beings are the few Chinese soldiers that watch over the dead town. They stand in vain, as there is nobody within whom they need to watch. A little to the east of Harbin the plague has made quite incredible ravages. All the intensity of the epidemic seems to have been concentrated at a locality called Ashishe. Here the number of the deaths amount to 400 daily. In the course of only a few weeks whole city quarters have completely died out. The utter helplessness of the population, the lack of adequate medical assistance, and the fanaticism of the Chinese priesthood—that fans the savage instincts of the ignorant rabble—combine to create a situation of terror such as can only be met with in those far-off old-world places of barbarism. The Chinese authorities have lost their heads entirely. In many places priests hold public discourses to the effect that China is visited by the plague as a heaven-sent punishment for having allowed the Europeans to settle among the Chinese. Only the destruction of the foreigners could free the country from the epidemic.

March 2nd.

## AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

*Compensating Dairymen.*

LAST summer an extensive outbreak of typhoid fever occurred among patrons of a particular dairy in Fitzroy, a northern suburb of Melbourne. The supply came from a farm a few miles out of the city, and it was proved that a typhoid carrier had been employed at this farm, and that there were several cases of ill-defined sickness among employees and children of the owner. The Board of Health quarantined the farm and destroyed the daily output of milk for some time, involving the owner in a very considerable loss. He subsequently applied for compensation, and this request was supported by a deputation of the Dairymen's Association. The Minister of Health declined to recognise the claim on the ground that there was plenty of evidence that the owner had not been sufficiently careful of his duty as a dairyman.

*Australian Meat.*

The Australian beef and mutton shipped to the Philippines under contract with the American army have given great satisfaction. Commissary-General Sharpe stated "frozen fresh beef of hind-quarters only and mutton were supplied from Australia in large quantities and were of universally good quality." Experiments were made with frozen beef that had been kept in cold storage for two years. Samples were sent to the army medical department and the Insular Bacteriological Bureau of Science, which reported as follows:—

The beef had none of the bacteria present in meat poisoning. The cooked meat (steak) lacked aroma, but had good flavour and compared favourably with fresh frozen beef, and the only gross evidences of long storage were slight discolourations of the fasciæ and a general loss of water.

*Contagious Dairy Disease.*

At the session of the Australasian Science Congress in Sydney, Professor Gilruth of Melbourne communicated a paper on an acute outbreak of inflamed udders due to B. lactis aerogenes. The symptoms were like those of ordinary garget, which was not recognised as contagious. The milking machine, which was badly kept, appeared responsible for spreading infection. Experimental inoculation of B. lactis aerogenes obtained from infected cows gave rise to acute inflammation of the particular quarter. The important point is that this bacillus is very common in piggeries and dairies, and might be the cause of most of the painful and swollen udders.

*Consumption.*

At the Sydney Science Congress Sir P. Sydney Jones read a paper dealing with the causes of consumptive incidence. He reviewed most of the accepted positions with regard to tuberculosis. He considered that where compulsory notification was in operation it was the bounden duty of the State to provide sanatoria and hospitals for advanced cases.

*"The Fly Peril."*

A somewhat sensational address was made by Dr. Burnett Ham, chairman of the Victorian Board of Health, at its last meeting, on the subject of disease transmission by flies. Dr. Ham urged a "crusade" against flies, and is having an illustrated wall card printed setting forth the dangers of allowing flies to breed without restraint and obtain access to food.

*Decline of Rabbits.*

The rabbit industry in Victoria is stated to be slowly but surely disappearing. The first export of frozen rabbits was made in 1894, in which year 14,928 rabbits were sent to England. Next year the total was 431,716. In 1900 the total was 5,678,224, and in 1905, 10,258,356. Since that year the total has gradually declined till last year it had come down to 2,841,648 rabbits exported. Exporters and agriculturists alike are pleased at this result. The former have all their available freezing plants occupied with meat and butter and cheese, while the latter view the gradual extinction of the rabbit pest with composure.

*Health of Western Australia.*

The annual report of the principal medical officer for Western Australia gives the population of that State as 274,755; the birth-rate 27·66, which is a decline of 3 per 1000 for the last 10 years. The death-rate was 9·85. Typhoid fever accounted for 3·07 per cent. of all deaths. No case of plague was notified. There is no system of sewerage anywhere in Western Australia, though one is being undertaken at Perth.

*Consumption Hospital.*

The hospital for advanced consumptives which is projected by the Victorian Government, and is to contain 100 beds, has been delayed in building owing to a difference in estimate of cost. The Government architects estimated the outlay at £10,000, but the lowest tender received was over £14,000. It has been decided to accept none of the present tenders, but to make some amendment of the plans and call for fresh tenders.

Feb. 4th.

# Obituary.

WILLIAM HENEAGE LEGGE, M.R.C.S. ENG., L.S.A.

THE death occurred at Ringmer, near Lewes, Sussex, on March 6th of Mr. William Heneage Legge, at the age of 53. The son of Dr. William Legge of Derby, and grandson of the Rev. William Legge, historian, of Fakenham, Norfolk, William Heneage Legge was educated at Trent College and under Dr. Reid at Ore, Hastings. He became a medical student at Westminster and took the diplomas of L.S.A. in 1880 and M.R.C.S. Eng. in 1881. The first Boer war broke out at this time and Mr. Legge went out as medical officer on

a troopship. Returning to this country he settled at Ringmer and besides a private practice held some public appointments and took an active part in public affairs. His knowledge of all things archæological in East Sussex was probably as great as that of any of his contemporary observers, and he was a frequent contributor to archæological journals on these subjects. The funeral took place at Ringmer on March 11th.

# Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At a meeting of the Council on March 9th the undermentioned diplomas were conferred upon the following gentlemen, who have now complied with the respective by-laws:—

*Diploma of Fellow.*—Ernest Marshall Cowell, M.D. Lond., L.R.C.P., M.R.C.S., University College Hospital; and Phirozshah Byramji Bharucha, L.M.S. Bombay, L.R.C.P., M.R.C.S., Bombay University and Middlesex Hospital.

*Licence in Dental Surgery.*—Thomas Benjamin Burke, Manchester University.

THE SMALL-POX EPIDEMIC IN LONDON.—During the past week there has been no marked change in the small-pox situation. On March 8th one fresh case (from Lewisham) and one death were registered. On March 9th there were five new cases, viz.:—Three from Poplar and one each from Shoreditch and Camberwell. On March 10th two new cases were notified, one from Poplar and one from Shoreditch, and on March 11th one from Hackney. At a meeting of the Metropolitan Asylums Board on March 11th Lord Donoraile, chairman of the statistical committee, gave out in answer to a request the following particulars in reference to the vaccination of the small-pox patients admitted at the South Wharf between Feb. 21st midnight and March 9th:—

There have been 52 genuine small-pox cases admitted. Of that number 36 were stated to have been vaccinated in infancy, of whom one has died; in three cases there was no evidence of vaccination, and two of those patients have died; 13 were not vaccinated, of whom five had died. The one patient vaccinated in infancy who died was aged 43 years; the two patients in whose cases there was no evidence of vaccination who died were aged 40 and 84 years respectively, and the five unvaccinated patients who died were aged respectively 1 month, 2 years and 4 months, 3 years, 4 years, and 25 years. Only one of the 36 patients said to have been vaccinated in infancy had been revaccinated before infection. He is a patient aged 10 years and is still alive. Two additional cases were admitted on Friday, but in those cases the condition as to vaccination is not yet ascertained.

On March 12th one case was reported from Shoreditch. No fresh cases were admitted on March 13th or 14th, the total under treatment being 48. This, with one new death, the tenth, makes a total of 58 genuine cases recorded up to March 15th. The London County Council at its meeting on March 14th unanimously resolved that for a period of three months chicken-pox should be made a notifiable disease, experience having proved that slight cases of small-pox are sometimes mistaken for chicken-pox. The satisfactory nature of the precautionary measures taken by the sanitary authorities is clearly shown by this slight activity in view of the extensive exposure that took place in many directions before the disease was recognised. In Stepney there has not been a genuine case of small-pox for 13 days—March 2nd was the last. There has been here no alteration or addition to the deaths from the report in our issue of last week.

THE ATTACK UPON THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.—A special court of governors of this hospital was held, under the presidency of Lord Peel, on March 8th, when the secretary read a report of the committee of management replying to the attack which had been made upon the hospital by *Mrs. Bull* and *John Bull*. The report reviewed all the charges that have been brought against the hospital in a way which convinced the meeting that their patients in the hospital are, and have been, treated in a manner reflecting the greatest credit upon the medical and nursing staff. The straightforward statement of the committee showed clearly that obviously unavoidable circumstances have been utilised for the purposes of sensational journalism. Dr. A. E. Garrod, the senior physician to the hospital, said that all the charges on investigation had proved to be utterly groundless. Sir Thomas Barlow, on behalf of the governors, moved a vote of confidence in the committee of management. This was seconded by Sir Trevor Lawrence and carried. Mr. Edmund Owen and Dr. D. B. Lees afterwards respectively moving and seconding a motion declaring the attack on the hospital to be unworthy of respectable journalism.

THE ANNUAL GENERAL MEETING OF THE ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—This meeting will be held on March 23rd at the Holborn Restaurant, London, at 3.15 P.M., when the election of officers and other business will be transacted. At 4.30 P.M. there will be a conference with delegates from other associations of medical men holding part-time appointments.

WILTSHIRE HOSPITALS AND THE KING EDWARD MEMORIAL.—£1069 have been collected in Swindon for the King Edward Memorial Fund, and this sum is to be devoted to the endowment of the Victoria Hospital.—It has been decided at Devizes that the memorial to the late King shall take the form of an extension scheme for the local hospital. Mr. A. Grant-Meek, the chairman of the institution, has given £500, and it is hoped that a substantial sum will be subscribed.

BIRMINGHAM AND MIDLAND COUNTIES SANATORIUM, BLACKWELL.—The forty-fifth annual report stated that there had been a substantial increase in the number of patients admitted, the total having reached 1755 with an average stay of 17·7 days as compared with 1672 in 1909. This was the highest number of admissions recorded. The average number of beds occupied varied from a minimum of 68·4 during the fourth quarter to the maximum of 99·9 in the third quarter. The average for the year was 85·2. The financial position was discouraging. Not only had there been a decrease in income of £6 2*s.*, but the expenditure had increased by £54 19*s.* 10*d.*, leaving an adverse balance on the management account of £117 11*s.* compared with £56 9*s.* 2*d.* in 1909.

THE ROYAL DENTAL HOSPITAL OF LONDON.—The annual general meeting of the governors of the Royal Dental Hospital of London was held on March 9th, when Mr. E. Lloyd-Williams, a vice-president of the hospital, occupied the chair. In presenting the report the chairman called attention to the fact that there was a mortgage of £38,623 on the hospital, for which a sum of £2655 had to be paid annually for interest and compulsory instalment of principal. Last year they were enabled to pay off an extra £1500 in addition to compulsory payments. The total sum received for the general fund was £7003, of which £2031 came from subscriptions. The number of patients treated during the year was 21,036 and the attendances were 56,209. The number of administrations of general anæsthetics was 12,081, involving about 111,258 individual operations.

THE ANNIVERSARY DINNER OF THE MEDICAL SOCIETY OF LONDON.—This society celebrated its 138th anniversary dinner at the Hôtel Métropole, London, on March 8th, under the chairmanship of the President, Mr. Charters J. Symonds. Covers were laid for more than 150 guests, and amongst the company present were the President of the Royal College of Physicians of London, the President of the Royal College of Surgeons of England, the President of the Royal Society of Medicine, the President of the Society of Tropical Medicine, the Master of the Society of Apothecaries, the Director-General of the Army Medical Service, the Inspector-General of the Navy Medical Service, the President of the Harveian Society, the President of the Hunterian Society, Professor A. Keith, Professor Howard Marsh, the Mayor of Marylebone, Dr. F. W. Mott, the President of the Ophthalmological Society, Dr. StClair Thomson, Sir John Tweedy, and Sir E. Venning. Sir Thomas Barlow proposed "The Medical Society of London" and congratulated the members on the prosperity of their society. Mr. Symonds, in replying, gave a most satisfactory account of the position of the society. Dr. Mott was then presented with the Fothergillian medal for his researches in the pathology of the nervous system, more especially in regard to syphilis. Dr. Mott, in his words of acknowledgment, rendered an eloquent tribute to the work which the London County Council are doing in the cause of scientific medicine. "The Guests" was the next toast, and was submitted by Dr. A. F. Voelcker. Dr. Goodhart responded to this toast, as also did the Mayor of Marylebone.

A DINNER TO SIR DAVID FERRIER.—A complimentary dinner is to be given by former students of King's College Hospital to Sir David Ferrier, F.R.S., to congratulate him on receiving the honour of knighthood. The dinner will be held on Wednesday, March 29th, and any King's man who may not have received an invitation is requested to communicate with the Honorary Secretary, Ferrier Dinner, King's College Hospital, London, W.C.

EASTBOURNE MEDICAL OFFICER OF HEALTH.—The town of Eastbourne becomes a county borough on April 1st next, and thus increased responsibility falls upon the heads of the various municipal departments. The town council, at its meeting on March 6th, decided to increase the salary of Dr. W. G. Willoughby as medical officer of health from £525 to £600 per annum, and as medical officer of the corporation sanatorium from £100 to £150 per annum, the increases to date from April 1st. Dr. Willoughby, the present President of the Society of Medical Officers of Health, has been medical officer of health at Eastbourne for 17 years.

THE BROWN DOG MEMORIAL.—On March 8th, at a meeting of the Battersea borough council, the law and general purposes committee reported that it had been asked by the donors of the Brown Dog Memorial for the return of the memorial and for the £300 which had been deposited with the council's bankers. The committee recommended that the brown dog and inscription should be destroyed and that the fountain should be retained and erected in a suitable place. No recommendation was made with regard to the £300 in view of the possibility of further legal liabilities. The report of the committee was adopted by 40 votes to 14.

FIFTH INTERNATIONAL CONGRESS FOR THALASSOTHERAPY (KOLBERG).—The Congress will take place at Kolberg in Prussia from June 5th to 8th next. It is under the protection of H.R.H. the Grand Duke of Mecklenburg-Schwerin. The committee of organisation includes the following gentlemen: Geh. Ob. Med.-Rat Professor Dr. Dietrich, 1st President; Geh. San.-Rat Dr. Röchling, 2nd President; and I. Bürgermeister Dr. Schmiedel, 3rd President. The secretaries are Dr. Kaminer, Herr Mann, general secretary of the Ostseebäderverband, and Dr. Margulies. The programme of the Congress is now prepared, and will be sent gratis by the committee of organisation upon application to the offices of the Congress, Potsdamerstrasse, 134b, Berlin, W.9.

BIRMINGHAM GENERAL HOSPITAL.—The board of management has recently issued the 131st annual report. The nursing staff has again been increased in order to reduce the working hours and to increase the time allowed for meals. The number of nurses is now 127. The enlargement of the X ray department and the more complete equipment provided has resulted in a considerable extension of the work, not only of the radiographic department but also in the treatment of lupus, skin diseases, &c. The necessity of treatment by radium was represented by the medical staff, and the board therefore entered into an arrangement to hire a quantity of radium on two days a week for six months. The number of in-patients under treatment last year was 5317, a decrease of 194, but the daily average was 308·5, an increase of 4·50.

CONVICTION OF A MEDICAL MAN FOR AN ATTEMPT TO PROCURE MISCARRIAGE.—At the recent assizes at Hertford, before Mr. Justice Bucknill, Mr. S. I. Lightfoot, a medical practitioner, was convicted and sentenced to five years' penal servitude upon an indictment charging him with using an instrument upon a young woman named Hill with intent to procure her miscarriage. It was not disputed that Hill, who is unmarried and lives in another town, went to the house of the accused, was examined by him, and that he used a catheter upon her which he left *in situ*, recommending her to return home and consult her usual medical attendant, or that premature confinement was caused. The defendant's case, however, was that eclampsia came on while the woman was in his consulting-room, and that he used the catheter as the nearest suitable instrument at hand in order to induce labour, sending her home because he could not keep her where she was; that entries in his books not stating the facts accurately were made in error by his wife; and that pressure of practice and forgetting the name of the medical man mentioned by his patient prevented him from informing that gentleman of what he had done. Leave to appeal against the conviction has been refused by the Court of Criminal Appeal.

A SOMERSET CENTENARIAN.—Mr. James Creedy, of Bridgwater, celebrated his hundredth birthday on March 6th.

PRESENTATION TO A MEDICAL PRACTITIONER.—Dr. L. S. McManus, one of the Direct Representatives of the medical profession on the General Medical Council, has for some months been prostrated by a severe illness. His many friends in Battersea, in order to show their sympathy in a practical manner, have presented him, through his son, with a cheque for £300, a pair of silver dishes, and an album containing an illuminated address. A bracelet has also been presented to Mrs. McManus.

A SOCIETY FOR THE STUDY OF HEREDITY IN BIRMINGHAM.—This society has been recently founded to study heredity in its bearings on the human race. It has for its President the Lord Bishop of Birmingham. The Right Hon. William Kenrick, Sir Oliver Lodge, Mr. Francis Meynell, and Mr. A. D. Steel-Maitland, M.P., are Vice-Presidents, and Mrs. Jordan Lloyd and Mr. H. Humphreys are the secretaries. The inaugural meeting was held on March 1st, when a large audience assembled to hear an address on "Human Heredity" by Professor J. Arthur Thomson.

# Parliamentary Intelligence.

## NOTES ON CURRENT TOPICS.

*The Naval Medical Service.*

Mr. MCKENNA, the First Lord of the Admiralty, makes interesting observations about medical matters concerning the navy in his statement explanatory of the Navy Estimates 1911-12. He remarks that effect has already been given to many of the recommendations of the committee appointed to inquire into the Naval Medical Service, but others of them are complicated by financial issues which remain for settlement. The right honourable gentleman does not specify the recommendations to which effect has been given. He states that he has for some time been giving his most earnest consideration to the serious problem of tuberculosis so far as it affects the seamen of the Royal Navy. He has caused an investigation to be made by the Medical Consultative Board into the means by which under the conditions peculiar to the naval service this disease can best be treated and its inception and spread checked. Mr. MCKENNA notes that arrangements have been made by the Admiralty with civil hospitals for the supply in the event of war of trained nurses who would form a reserve of additional trained nurses. The new force will be known as Queen Alexandra's Royal Naval Nursing Service Reserve.

*Education (Administrative Provisions) Bill.*

The Education (Administrative Provisions) Bill, which has been presented in the House of Commons by Mr. TYSON WILSON, acting in concert with members of the Labour Party, deals with the relation of the medical inspector of school children to the feeding of underfed children. The scope of the Bill is explained in a memorandum. It sets out that the object of the Bill is to remove from the education authority the final responsibility for saying whether a child is or is not underfed, and to impose that duty upon the medical inspector (should one exist), the medical officer of health, or other medical official. As the law stands, it rests with the education authorities to say whether there are or are not underfed children attending their schools, and in consequence whether the Act should or should not be put into operation. This, says the memorandum, has led to uncertainty of administration.

Clause 1 of the Bill enables the education committee, the school managers, and head teachers to ask the medical man to examine the child.

In Clause 2 it is laid down that the medical inspector must examine a child alleged, by the persons authorised, to be suffering from underfeeding, and the head teacher is empowered, pending the report of the inspector, to make temporary provision for the child. The second subsection annuls the limitation of the rate imposed by the third section of the Education (Provision of Meals) Act, 1906, and the third section legalises the feeding of children during the school vacation.

Other clauses in the Bill propose that the medical inspector should present an annual report on the physical condition of children attending school in his area, and that an appeal from the decision of the medical inspector to the Board of Education should be given in certain circumstances.

*Rag Flock Bill.*

A Bill has been introduced into the House of Commons by Mr. JOHN BURNS to prohibit the sale and use, for the manufacture of certain articles, of unclean flock manufactured from rags.

*Sale of Margarine Bill.*

Mr. KILBRIDE has presented in the House of Commons a Bill "to provide for the further prevention of the fraudulent sale of margarine." It was read a first time.

## HOUSE OF COMMONS.

WEDNESDAY, MARCH 8TH.

*Medical Practitioners and the Rebate on Motor Spirit.*

Mr. GINNELL asked the Secretary to the Treasury, in view of the fact that the collection of motor spirit duty from manufacturers and dealers was the duty of the Revenue Department, by what authority did that Department, on failing to collect from those people, refuse the rebate due to a medical practitioner who was not bound to prove the payment of duty by those people; and whether the Chancellor of the Exchequer had sanctioned the refusal in such cases.—Mr. HOBHOUSE replied: In view of the fact that large quantities of motor spirit on which duty has not been charged, and is not chargeable, are held in stock throughout the country, rebate is refused unless the Commissioners of Customs and Excise are satisfied that duty has in fact been paid to the Crown in respect of quantities used by claimants of allowances on the duty. This is in accordance with the intentions of my right honourable friend the Chancellor of the Exchequer as embodied in the Finance (1909-10) Act, 1910. The identification of spirit on which duty has actually been paid can only be completed by the Customs and Excise officials on their being supplied with full information regarding the sources from which such spirit has been derived.

THURSDAY, MARCH 9TH.

*Typhoid Fever in the Bog Area of Glones.*

Mr. DUFFY asked the Chief Secretary to the Lord Lieutenant of Ireland whether any preventive measures had been taken by the Government to prevent a recurrence of the typhoid epidemic which visited and ruined so many families in the bog area of Glones, Athenry, all through last year; whether he was aware that the tenants were living in a wilderness of marsh and bog, and in constant terror of invading disease; whether the Browne estate in the district had been offered to the Commissioners; and whether, in view of the urgency of dealing with this fever-threatened district as soon as possible, he would direct the attention of the Estates Commissioners and the Congested Districts Board to the exceptional circumstances of this village with a view of removing the people on to the lands of the Browne and Monahan estates.—Mr. BIRRELL answered: Five cases of typhoid fever which occurred in two families at the place referred to were notified to the Local Government Board during the year 1910. The usual precautionary measures were carried out. It devolves on the sanitary authority and their officers, and not upon the Local Government Board, to take preventive action in connexion with outbreaks of infectious disease. The Glones section of the Browne estate has been offered to the Congested Districts Board, and the offer will be considered by them. The Monahan estate was offered for sale in 1906, but the offer was declined by the Board.

*Beri-beri Cases at Galway.*

Mr. PATRICK WHITE asked the Chief Secretary to the Lord Lieutenant of Ireland, as President of the Local Government Board, whether there were some cases of the disease known as beri-beri at present under treatment in the isolation hospital, Galway; whether he would state the number affected with the disease; the numerical strength of the nursing staff, and what provision had been made for their accommodation; whether one of the patients became delirious, and at the time he became so affected whether there was any male attendant in the hospital, or how he was controlled; whether the hospital was at times partly surrounded by water, and what means of ingress or egress there was to it from the mainland; and whether any precautions had been taken to provide male attendants in the event of any of the other patients becoming delirious.—Mr. BIRRELL said in reply: There are at present four patients from a Norwegian ship under treatment in the intercepting hospital in Galway, three of whom are undoubtedly suffering from beri-beri, whilst the other is under observation. The Local Government Board understands that the patients are in a well-ventilated ward in every way suitable for their treatment, and are under the charge of three qualified nurses, who occupy another ward and have the use of the kitchen. One patient became suddenly delirious and violent, but was got under control by the nurses and had become quiet before the medical officer arrived. The latter has since procured the assistance of two male attendants, one of whom will at all times be on duty and the other easily available. The hospital is built on the mainland, with the sea on two sides, and is accessible by foot, car, or boat.

*The Isolation of Small-pox in Scotland.*

Dr. A. P. HILLIER asked the Lord Advocate whether he was aware that the Local Government Board for Scotland, in a recent communication to the Public Health Committee of Edinburgh and Leith, had in suggesting the provision of further hospital accommodation for small-pox, alleged as one of their reasons for doing so the danger to the community consequent on the slackening of compulsory vaccination; and, if so, what steps the Local Government Board for Scotland proposed to take to bring this danger to the notice of other sanitary authorities.—Mr. URE replied: The honourable Member's inquiry is probably based on the wording of a report obtained by the Local Government Board for Scotland, which was communicated by it to the local authority of the city of Edinburgh. I am informed that the Board, on Feb. 28th, 1911, communicated with all the local authorities in Scotland that did not appear to have made provision for the isolation and treatment of cases of small-pox, requesting to be informed of the steps they proposed to take to secure that such provision would be available in the event of a case or cases of small-pox occurring.

Dr. HILLIER: Can the right honourable gentleman say that in that communication the ground alleged for making this recommendation was the increasing danger from the diminution in the number of vaccinations?—Mr. URE: I am not aware.

*Notification of Births Act.*

Replying to a question put by Mr. WEDGWOOD, Mr. BURNS wrote that the Notification of Births Act had been adopted for, or put in force in, 271 areas of local government. These included 29 metropolitan boroughs (including the City of London), 53 county boroughs, 54 non-county boroughs, 91 urban districts other than boroughs, and 44 rural districts. The right honourable gentleman appended to his answer the following tables:—

*County Boroughs in which the Notification of Births Act is in Force, with the Infant Mortality Rates (Deaths under One Year of Age per 1000 Births) in 1905 and 1909.*

| Name of county borough. | Infant mortality. 1905. | 1909. | Name of county borough. | Infant mortality. 1905. | 1909. |
|---|---|---|---|---|---|
| Bath | 91 | 83 | Newport (Mon.) | 125 | 115 |
| Birmingham | 154 | 134 | Northampton | 126 | 110 |
| Blackburn | 146 | 126 | Norwich | 174 | 119 |
| Blackpool | 133 | 112 | Nottingham | 155 | 150 |
| Bolton | 167 | 128 | Oldham | 150 | 119 |
| Bootle | 156 | 122 | *Portsmouth | 133 | 96 |
| Bradford | 144 | 116 | Preston | 154 | 136 |
| Brighton | 101 | 96 | Reading | 121 | 95 |
| Burnley | 173 | 156 | Rochdale | 133 | 104 |
| *Burton-upon-Trent | 87 | 102 | Rotherham | 123 | 116 |
| Bury | 147 | 130 | St. Helens | 134 | 150 |
| Cardiff | 118 | 103 | Sheffield | 167 | 118 |
| *Chester | 122 | 118 | Smethwick | 137 | 113 |
| Croydon | 95 | 80 | Southampton | 132 | 106 |
| Derby | 151 | 123 | Southport | 113 | 103 |
| Dudley | 167 | 140 | Stockport | 168 | 132 |
| Exeter | 122 | 99 | Stoke-upon-Trent | 147 | 126 |
| *Great Yarmouth | 132 | 125 | Swansea | 131 | 159 |
| Grimsby | 174 | 118 | Wallsall | 141 | 139 |
| Halifax | 131 | 97 | *Warrington | 147 | 130 |
| Ipswich | 144 | 92 | West Bromwich | 146 | 123 |
| Kingston-on-Hull | 152 | 114 | West Ham | 153 | 124 |
| Lincoln | 148 | 82 | *Wigan | 164 | 173 |
| Liverpool | 153 | 144 | Wolverhampton | 137 | 148 |
| Merthyr Tydfil | 193 | 143 | Worcester | 154 | 101 |
| Middlesbrough | 173 | 158 | York | 129 | 99 |
| Newcastle-upon-Tyne | 135 | 119 | | | |

* Act adopted since 1909.

*County Boroughs in which the Notification of Births Act is not in Force, with the Infant Mortality Rates in 1905 and 1909.*

| Name of county borough. | Infant mortality. 1905. | 1909. | Name of county borough. | Infant mortality. 1905. | 1909. |
|---|---|---|---|---|---|
| Barrow-in-Furness | 135 | 81 | Leeds | 151 | 122 |
| Birkenhead | 127 | 123 | Leicester | 148 | 127 |
| Bournemouth | 83 | 100 | Manchester | 157 | 134 |
| Bristol | 122 | 100 | Oxford | 116 | 75 |
| Canterbury | 119 | 73 | Plymouth | 135 | 131 |
| Coventry | 108 | 97 | Salford | 148 | 141 |
| Devonport | 113 | 96 | South Shields | 146 | 137 |
| Gateshead | 138 | 112 | *Sunderland | 142 | 135 |
| Gloucester | 118 | 95 | Tynemouth | 153 | 129 |
| Hastings | 113 | 79 | West Hartlepool | 146 | 113 |
| *Huddersfield | 119 | 95 | | | |

* Compulsory notification of births has been in force under the provisions of local Acts in Huddersfield since 1906 and in Sunderland since 1907.

*The Adulteration of Food.*

Mr. CHARLES BATHURST asked the President of the Local Government Board whether, in the contemplated amendment of the law relating to the adulteration of human foods, he would consider the advisability of including within the term adulteration not merely the addition to any article of food of some extraneous matter of a possibly deleterious character, but also the abstraction from flour, milk, rice, and other natural food products of ingredients of high food value for the sake of improved appearance or increased commercial profit without any intimation to the consumer, by trade description or otherwise, that such abstraction had taken place.—Mr. BURNS said in reply: The subject is one which must be considered in connexion with proposals for the amendment of the Sale of Food and Drugs Acts.

*Plague amongst Rats in East Anglia.*

Mr. GEORGE ROBERTS asked the President of the Local Government Board whether he was yet in a position to state the results of investigations made into the existence of plague among rats in East Anglia, or did he contemplate presenting a report to Parliament thereon; and would he consider the advisability of continuing these examinations in the summer and autumn, as such periods were regarded as the most dangerous for the spread of plague infection.—Mr. BURNS answered: I am expecting to receive very shortly a report on the investigations referred to. Until the report is before me I am not able to say what steps should be taken with regard to its publication. The procedure to be adopted during the summer and autumn will be carefully considered by me.

*Mortality of Poor-law Children.*

Mr. WEDGWOOD asked the President of the Local Government Board, with reference to the mortality of children under five in Poor-law institutions, whether he had yet been able to obtain fuller statistics to supply the want noted by the Royal Commission; and further, what the result had been of Dr. Darwall Smith's inquiry as to the causes of the heavy mortality.—Mr. BURNS wrote in reply: I am obtaining some statistical information with reference to infant mortality in Poor-law institutions, but it is not yet complete. I understand that the results of Dr. Darwall Smith's investigations will not be ready for some time.

*Deaths from Chicken-pox.*

Mr. CRAWSHAY-WILLIAMS asked the President of the Local Government Board whether he would state the number of deaths of children under the age of 15 years who were certified to have died from chicken-pox in England in the years 1908 and 1909, and what was their vaccinal condition; whether it was still the view of the Registrar-General that chicken-pox was usually so trifling an ailment, and so rarely if ever fatal, that it might be assumed with much probability that the greater part of the 100 or so deaths that year after year are referred to this cause were in reality cases of small-pox, as stated in his 46th Report; and what was the reason for the omission of the reference to chicken-pox from the 72nd Annual Report of the Registrar-General, after a similar reference had appeared for so many years.—Mr. BURNS furnished the following written answer: The numbers of deaths certified as resulting from chicken-pox of children under 15 years of age in England and Wales were 93 in 1908 and 94 in 1909. The vaccinal condition of these children is not stated in the death returns. With regard to the last part of the question, it is true that the statement quoted was made in the report for the year 1883, but subsequent experience has not shown that there is any evidence that any considerable proportion of the recorded mortality from chicken-pox is really due to small-pox. Although chicken-pox in the vast majority of cases is a very mild disease, it is well known that severe cases occasionally occur which may be fatal.

*A Case of Vaccination at Barnsley.*

Sir JOSEPH WALTON asked the President of the Local Government Board whether he was aware that a public vaccinator of the Barnsley union attended at the house of Mrs. Haigh of Barnsley after she had legally made a statutory declaration of conscientious objection under the Vaccination Act, 1907, and vaccinated the child in respect to whom such declaration of objection was made; and what steps, if any, he proposed to take, not only with regard to the action of the public vaccinator in question, but also of that of the vaccination officer of the union, who had entered the name of the child on the list he sent to the doctor, although he had received the certificate of declaration from the child's mother.—Mr. BURNS (by written answer) replied: I have seen a newspaper account of this case, and the statement of facts given in the newspaper agrees generally with that in the question. It appears that the woman's husband had left her, but that this information was not given to the vaccination officer. When a husband and wife are living together the husband is the person entitled to make the declaration of conscientious objection. According to the newspaper account the woman stated at the meeting of the board of guardians when the case was considered that, whilst she believed in vaccination, she did not want the child vaccinated, as it might have interfered with her work, and also that she consented to have the child vaccinated. On the information at present before me it does not appear necessary to take any further steps in regard to the case.

MONDAY, MARCH 13TH.

*The Midwives Act.*

In reply to Dr. ADDISON, Mr. BURNS said: The Government is not without hope that it may be possible to introduce a Bill to amend the Midwives Act this session.

*The Sanitary Conditions of Wye.*

Dr. ADDISON asked the President of the Local Government Board whether he had received complaints from the inhabitants of Wye, Kent, as to the insanitary conditions prevailing there; whether the local authority was taking suitable and efficient measures to deal with the existing nuisances; and whether he would direct one of the medical officers of the Local Government Board personally to inspect the sanitary arrangements and report upon what measures were necessary to be taken in the interests of the public health.—Mr. BURNS replied: I have received complaints in regard to Oxenturn, Lane, and Wye, and I have directed one of the Board's inspectors to visit the locality and report to me on the matter.

*Vaccination of Children.*

Dr. HILLIER asked the President of the Local Government Board whether, in view of the recent outbreak of small-pox, and the continued increase in the numbers of children exempted from vaccination, he would give instructions to have issued with the vaccination notices a circular pointing out the value of vaccination as a means of preventing the contraction of small-pox.—Mr. BURNS said in reply: The suggestion made by the honourable member is not one which I am able to accept.

Dr. HILLIER: Is the right honourable gentleman aware that in some localities 50 per cent. of the children are exempt from vaccination?—Mr. BURNS: I am aware exemptions are increasing, but I am not aware that they are 50 per cent.

Dr. HILLIER: Does the right honourable gentleman intend to take steps to put a stop to this?

No reply was given.

Mr. WEDGWOOD asked the right honourable gentleman whether he could state the number of public vaccinators who had been appointed as medical inspectors for elementary schools under the Education (Administrative Provisions) Act by local education authorities; and whether the Local Government Board agreed that these two offices should be held by the same person.—Mr. BURNS answered: I cannot state the number of public vaccinators who have been appointed as medical inspectors of school children. The Local Government Board have stated that both they and the Board of Education consider that the office of medical inspector of school children may with advantage be combined with the office of medical officer of health in a country district, and that amongst the other public offices which a medical officer of health may be allowed to hold is that of public vaccinator.

Mr. RAMSAY MACDONALD asked the President of the Board of Education whether he was aware that the Education Committee of the London County Council had resolved to recommend such Council to rescind their resolution of April, 1906, with reference to the examination and vaccination of children, and that the Education Committee further advised the exclusion from the public elementary schools of those children who were unvaccinated; and whether he would take immediate steps to deal with this proposal.—Mr. RUNCIMAN said in reply: I have seen a newspaper report of the proceedings of the Education Committee, from which I understand that they are recommending that the resolution referred to should be rescinded. The report states that they also recommend that no examination of children, for the purpose of ascertaining which of them have been vaccinated, should be made without the written consent of the parents. I understand that the recommendation of the Education Committee has not yet been adopted by the Council. I can only deal with the matter if there is an infringement of the Code.

TUESDAY, MARCH 14TH.

*The Dresden Hygiene Exhibition.*

Sir HERBERT RAPHAEL asked the First Lord of the Admiralty whether his attention had been called to the fact that several of the medical officers of his department had resigned their membership of the British committee formed for the purpose of preparing a British exhibit at the International Hygiene Exhibition at Dresden, on learning of the decision of His Majesty's Government not to support this exhibition; and whether, in view of the recent expression of commendation addressed by the President of the Board of Trade in the name of the Government to the chairman of the committee, he would advise these gentlemen to join the committee again and assist in preparing a suitable exhibit in connexion with diving, naval hygiene, and other cognate matters.—Mr. MCKENNA replied: I am unaware whether naval medical officers have at any time taken part privately in the work of the committee. None have joined it officially. The Admiralty cannot undertake to send an exhibit, and I regret therefore that I cannot act on the suggestion contained in the second part of the question.

Mr. BYLES asked the President of the Board of Education whether he had had his attention directed to the fact that the subject of medical inspection of school children, and the treatment of children found defective at the inspection, would be illustrated and discussed at the forthcoming International Hygiene Exhibition at Dresden; and whether he proposed to prepare an exhibit and to send delegates to the associated congresses.—Mr. RUNCIMAN replied: I have heard that these subjects are to be dealt with. I cannot undertake to send an exhibit. I do not understand that the Board has been asked to send a delegate, but I shall, of course, be prepared to consider any invitation to do so.

# Appointments.

*Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to* THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

ALLINGHAM, HENRY REGINALD, M.B., B.S. Lond., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health of Totnes, Devon.

BALFOUR, T. STEVENSON, M.D., C.M. Edin., has been appointed Medical Officer and Public Vaccinator for the No. 2 District of the Chard (Somerset) Union.

# Births, Marriages, and Deaths.

## BIRTHS.

BARRETT.—On March 7th, at Rysseldene, Colwyn Bay, North Wales, the wife of W. Ernest Barrett, F.R.C.S., of a daughter.

BUCKLEY.—On March 13th, at The Ropewalk, Nottingham, the wife of Dr J. C. Buckley, of a daughter.

CARRUTHERS.—On March 10th, 1911, at Moody Hall, Congleton, the wife of E. J. W. Carruthers, M.D., of a daughter.

HEDLEY.—On March 15th, 1911, at 11, John-street, Berkeley-square, W., the wife of John Prescott Hedley, M.A., M.B., M.C. Cantab., of a son.

HODGSON.—On March 12th, at The Crescent, Salford, Lancs, the wife of Stanley Hodgson, M.D., B.S. Lond., &c., of a son.

MYLES.—On March 8th, at Clifton, Bristol, the wife of Staff-Surgeon T. W. Myles, R.N., of a daughter.

SMITH.—On March 11th, at 229, Balham High-road, S.W., the wife of Edwin Smith, M.D. Lond., Barrister-at-Law, of a daughter.

TALLENT.—On March 8th, at Walton Lodge, Chislehurst, the wife of J. H. Tallent, M.B. Cantab., M.R.C.S., of a son.

## DEATHS.

BOSSON.—On March 11th, at Lanby Hall, Alford, Lincs, George Bosson M.R.C.P., aged 66 years.

GILLATT.—On March 8th, at Cairo, Captain W. Harold Gillatt, R.A.M.C.

GORDON.—On Feb. 28th, at his residence, Laurel Cottage, Dalwood Dorset, John Hurd Gordon, L.R.C.P., in his 51st year.

SAFFERY.—On March 12th, at Talfourd-road, Camberwell, S.E., Frank Golder Saffery, M.R.C.S., L.R.C.P Lond., in his 42nd year.

*N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths*

# Notes, Short Comments, and Answers to Correspondents.

## RATS AND THE PLAGUE: THE PROPOSED PORT OF LONDON BY-LAWS.

THERE have been issued in the *Gazette* the following by-laws proposed by the Port of London Authority "for the prevention of an outbreak of plague amongst rats at the docks":—

1. All rope and mooring tackle for securing any vessel either to the shore or to mooring buoys shall be fitted with such effective guards as will prevent access of rats from the vessel to the shore. For any breach of this by-law the master of the vessel shall be liable to a penalty not exceeding £5.

2. All possible means shall be adopted for catching and destroying rats during the stay of any vessel in dock. All empty cases and barrels shall be examined before being landed to ensure that no rats are contained therein. Any rats caught on board the vessel shall be killed, then placed in a bucket of strong disinfecting solution, and afterwards burnt in the vessel's furnace. No rats, alive or dead, shall be removed from the vessel. For any breach of this by-law the master of the vessel shall be liable to a penalty not exceeding £5.

3. When the discharge of cargo or the landing or embarking of passengers is not proceeding one gangway only shall be permitted to afford means of communication between any vessel and the shore. The end of the gangway near the vessel shall be whitened for a length of 10 ft. For any breach of this by-law the master of the vessel shall be liable to a penalty not exceeding £5.

After March 13th, for one month, any person may make, in writing to the Board of Trade, any representations respecting these proposals.

## THE LATE DR. PIFFARD OF NEW YORK.

Dr. George Henry Fox of New York, in the *Journal of Cutaneous Diseases* for February, gives some reminiscences of the well-known dermatologist, the late Dr. Henry Grainger Piffard, in which he tells two amusing stories about him. Dr. Piffard began to collect foreign works on skin diseases. He was a fair German and a better French scholar, but knew very little of Italian. To supply this deficiency he at once subscribed for one or two Italian medical journals, selected a teacher, and attacked the language with his customary vigour. Happening to run across an advertisement of some book, entitled something like "*Trattato della Pelle et cetera*," he gave his bookdealer an order for it. The bookdealer, in a polite note, informed him that this was an expensive work, published by the Italian Government, and that it would take several weeks to import it. Piffard replied in language more vigorous than polite—"Expense be damned"; when he wanted a book he expected his dealer not to talk about it but to get it. In about two months, during which time his knowledge of Italian had rapidly increased, the book arrived and with it a bill for about £12. To his surprise and dismay he discovered at first glance that it was not a strictly dermatological work, but an elegantly bound and elaborate treatise on the tanning of hides.

The other story illustrates well the fact that *non omnia possumus omnes*. Dr. Piffard was a most versatile man, and in his ample affections for hobbies embraced many mistresses, including microscopy, medical politics, botany, canoeing, photography, bicycling, fishing, rifle shooting, mycology, radiotherapy, Esperanto, &c., with all of which he acquired some appreciable proficiency. The only thing he ever attacked to meet with signal defeat was music. When a young man Dr. Piffard was seized by the then prevailing craze to play the banjo. Dobson or some other professor was advertising proficiency in six easy lessons. Piffard, entirely unaware of the important fact that he had little or no music in his soul, decided to court the "heavenly maid" in her guise of sheepskin and catgut. He called on the professor, bought an expensive instrument, took his first lesson, and started home with high hopes and a small music-book. The latter he read carefully, and doubtless committed to memory. The position of his fingers on the frets, as shown him by the professor, he practised through many spare hours for a week, and then went proudly to his second lesson, eager to show how much he had accomplished. The professor listened to his pupil's performance with an expression of sober surprise. Then seizing the banjo he strummed it for a few minutes and inquired: "Doctor, do you know what tune I am playing?" "No, I don't," said Piffard with perfect truthfulness. "Well, Doctor, there is no use in going any further. I just played 'Carry me back to Ole Virginny,' the tune you have been practising for a week—and will never learn. Now, I'll buy your banjo back for half price and charge you nothing for the lessons, provided you will never tell anybody that you were a pupil of mine."

## ENAMELLED STEEL WARE AND APPENDICITIS.

WE have been requested by Messrs. Oscar Moenich and Co., Limited, to publish the following note upon an action brought by Messrs. Baumann Brothers, manufacturers of "Lion and Mug" brand enamelled steel ware, in the Fourth Chamber of the Commercial Court at Leipzig on Dec. 22nd, 1910. The note says that an injunction was granted against a defendant—subject to a penalty of £50 for each contravention—to repeat or circulate the statement that splinters of enamel were the cause of appendicitis or other intestinal disorders. The defendant was also condemned to pay the plaintiff's costs, and the plaintiff was authorised to publish the court's decision within one month in an issue of the *Leipziger Neuesten Nachrichten* at the expense of the defendant.

*Admirer.*—We fear we can give no advice in the circumstances, which clearly are a matter for our correspondent's own discretion. A solicitor will advise him whether legal penalties would follow his suggested action; to us it certainly seems that they might. For the rest he must consider whether the action of his employer in breaking the understood relations between professional men, as he alleges to have been the case, justifies the employed in going back on his word.

*Inquirer.*—The general answer is that the practitioner cannot be bound in such a way. Obligations, however, may arise which he would find it morally and practically unable to neglect. Will our correspondent (of course in confidence) state any particular case in which he is interested?

*S. of Pendleton.*—If the writer desires comment on his communication he must furnish us with his name and address for our information.

*M.D., D.P.H. Camb.*—We will try to obtain further information for our correspondent.

**COMMUNICATIONS not noticed in our present issue will receive attention in our next.**

## A DIARY OF CONGRESSES.

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced for March, and April, 1911:—

March 23rd (Paris).—First Congress of French Medical Journalists.
" 28th–April 25th (Tunis).—Exhibition of Hygiene.
April 4th–7th (London).—Fourth Annual Nursing and Midwifery Conference and Exhibition.
" 18th–20th (Paris).—Third Congress of Physiotherapy of French-speaking Physicians.
" 18th (Berlin).—Tenth Congress of the German Orthopædic Surgery Society.
" 19th–22nd (Berlin).—German Surgical Congress. (Fortieth Annual Meeting.)
" 19th–22nd (Wiesbaden).—Twenty-eighth German Congress of Internal Medicine.
" 20th–22nd (Groningen).—Thirteenth Nature and Medical Congress.

Medical Annals, Monthly Cyclopædia and Medical Bulletin, Detroit Medical Journal, Archives of Pediatrics, Review of Neurology and Psychiatry, Proceedings of the Canal Zone Medical Association, Polyclinic, Medical Review, Knowledge, School Hygiene, The Photographic Monthly, Bio-Chemical Journal, British Journal of Dermatology.

# Medical Diary for the ensuing Week.

## SOCIETIES.

**ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W. (temporary address during building of new house).**

TUESDAY.

THERAPEUTICAL AND PHARMACOLOGICAL SECTION (Hon. Secretaries—H. Charles Cameron, H. H. Dale): at 4.30 P.M.

*Papers:*

Dr. W. Langdon Brown: An Enquiry into the Value of Rectal Feeding.

Dr. D. V. Cow: The Reaction of Arteries to Certain Drugs.

PATHOLOGICAL SECTION (Hon. Secretaries—Charles Bolton, J. C. G. Ledingham): at 8.30 P.M.

Mr. C. Gordon Watson: Case of Resection of Cæcum and Ascending Colon showing Chronic Hypertrophy of the Mucous Membrane with Stenosis Simulating Cancer.

Dr. Coats and Dr. Forbes: The Relation of the Meningococcus to Pseudoglioma.

Dr. Morgan: The Gall-bladder Lesion in the Typhoid-carrier Rabbit.

Dr. Andrewes: The Inhibition of Pigment production in B. Prodigiosus by B. Fæcalis Alkaligenes.

Dr. H. R. Dean: On the Relation of Specific Precipitation to Complement-fixation.

FRIDAY.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN (Hon. Secretaries—J. P. Lockhart Mummery, T. R. Whipham, G. S. Haynes) at 11, Chandos-street, W.: at 4.30 P.M.

*Cases:*

Dr. Langmead: (1) Achondroplasia; (2) Myopathy (Landouzy-Déjerine variety).

Mr. R. G. Hann: Multiple Exostoses.

Dr. J. D. Rolleston: Inherited Syphilis and "Blue Sclerotics."

*Papers:*

Dr. David Forsyth: The History of Infant Feeding from Elizabethan Days.

Dr. Milne: A Plea for the Home Treatment and Prevention of Measles.

EPIDEMIOLOGICAL SECTION (Hon. Secretaries—W. H. Hamer, G. S. Buchanan): at 8.30 P.M.

*Paper:*

Dr. W. H. Hamer: Typhoid Carriers and Contact Infection: Some Difficulties Suggested by Study of Recent Investigations carried out on "Living Lines."

**ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.**

MONDAY.—8 P.M., Prof. J. A. Fleming: Applications of Electric Heating. (Cantor Lecture IV.)

**CHELSEA CLINICAL SOCIETY, Chelsea Dispensary, Manor-street, King's-road, S.W.**

TUESDAY.—8.30 P.M., Annual Clinical Debate on the Treatment of Colitis (opened by Dr. J. W. Eyre on Some Points in the Bacteriology of Colitis and its Treatment by Bacterial Vaccines, and Mr. P. L. Mummery on the Surgical Treatment of Colitis). Followed by a General Discussion. Open to all members of the Medical Profession.

**MEDICO-LEGAL SOCIETY, 11, Chandos-street, Cavendish-square, W.**

TUESDAY.—8.30 P.M., Mr. H. W. Gadd: How Far can the Abuse of Drugs be Prevented by Law?—Dr. Tunnicliffe: Patent Medicines.

**HUNTERIAN SOCIETY, London Institution, Finsbury-circus, E.C.**

WEDNESDAY.—8.30 P.M., Dr. D. Windle: The Respiratory Relationships of Pulsus Alternans.—Mr. R. Warren: Punctured Wounds of the Heart.

**CHILD STUDY SOCIETY, LONDON, 90, Buckingham-Palace-road, S.W.**

THURSDAY.—6.30 P.M., Annual General Meeting. 7.30 P.M., Mr. W. H. S. Garnett: Educational Possibilities of the Boy Scout Movement.

## LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

**ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East.**

TUESDAY.—5 P.M., Dr. A. F. Hertz: Sensibility of the Alimentary Canal in Health and Disease (Goulstonian Lecture).

THURSDAY.—5 P.M., Dr. J. M. Bruce: Clinical Study of Cardiovascular Regeneration (Lumleian Lecture).

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.**

MONDAY.—4 P.M., Mr. J. E. R. MacDonagh: Clinique (Skin). 5.15 P.M., Lecture:—Dr. J. L. Bunch: Some Common Skin Diseases in Children and their Treatment.

TUESDAY.—4 P.M., Dr. L. Smith: Clinique (Medical). 5.15 P.M., Lecture:—Dr. S. R. Wells: Angina Pectoris.

WEDNESDAY.—4 P.M., Mr. G. E. Waugh: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. G. H. Savage: Morbid Mental Growths.

## EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.*

*Lectures, original articles, and reports should be written on one side of the paper only,* AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale and advertising departments of* THE LANCET *should be addressed "To the Manager."*

*We cannot undertake to return MSS. not used.*

## MANAGER'S NOTICES.

### THE INDEX TO THE LANCET.

The Index and Title-page to Vol. II. of 1910 were given in THE LANCET of Dec. 31st, 1910.

### VOLUMES AND CASES.

VOLUMES for the second half of the year 1910 are now ready. Bound in cloth, gilt lettered, price 16*s.*, carriage extra.

Cases for binding the half-year's numbers are now ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

### TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

| FOR THE UNITED KINGDOM. | | TO THE COLONIES AND ABROAD. | |
|---|---|---|---|
| One Year ... ... ... | £1 1 0 | One Year ... ... ... | £1 5 0 |
| Six Months ... ... ... | 0 12 6 | Six Months ... ... ... | 0 14 0 |
| Three Months ... ... | 0 6 6 | Three Months ... ... | 0 7 0 |

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rate of pay, including allowances, is less than Rs. 50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

### TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at these rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

# The Milroy Lectures

ON

# ANKYLOSTOMA INFECTION.

*Delivered before the Royal College of Physicians of London on March 2nd, 7th, and 9th, 1911,*

BY A. E. BOYCOTT, M.A., D.M. OXON.,
LECTURER ON PATHOLOGY, GUY'S HOSPITAL.

## LECTURE II.[1]

*Delivered on March 7th.*

### THE DIAGNOSIS OF ANKYLOSTOMA INFECTION.

MR. PRESIDENT AND GENTLEMEN,—In the presence of well-marked anæmia, the only essential in the diagnosis of ankylostoma infection is that the possibility of a parasitic anæmia should be in one's mind. The disease was long unrecognised in Cornwall because it never occurred to anyone that it might be ankylostomiasis; it might, indeed, with some luck have gained a footing in medical literature as "Dolcoath anæmia," the chief characteristics being that it was confined to men working underground and that it was completely refractory to iron and arsenic. One case, at least, whose chief symptoms were dyspnœa and palpitations, went through the hands of several London consultants, whose opinions varied between dyspepsia and cardiac neurosis. Directly the idea that ankylostoma might be at the bottom of the matter occurred to anyone—in the present instance, to J. S. Haldane—the stools were examined and found to be full of eggs, and so the mystery was cleared up. In the same way in Porto Rico in 1899 one-third of 36,000 deaths were due to "anæmia," which was supposed to be caused by poor food and unhygienic conditions; it was only towards the close of that year that Ashford found that the condition was constantly associated with an eosinophilia, was by this led to examine the fæces, and so demonstrated that this enormous mortality was due to ankylostomiasis. The fact that the parasite occurred in the Southern United States had been known to the curious for a long time before Stiles in 1901 drew attention to the fact that it was the cause of serious endemic disease among the whole agricultural population.

In definite cases of ankylostomiasis there is no difficulty in making the definitive diagnosis of ankylostoma infection. The eggs are quite different from those of any other human parasite and occur in the stools in large numbers. If confusion arises, it is generally from some of the vegetable remains which one finds with all sorts of queer objects (mites, snails' tongues, &c.) in fæces. It is, however, obvious that it is not always easy to decide whether all or some of the illness in any given case of infection is due to the worm. This is especially difficult where, as, for example, in Assam, nearly all the natives are infected, and other diseases, such as malaria and kala-azar, are common enough. Quite recently, for example, Noc[2] has pointed out that in Cochin-China the difficulties of estimating the share of ankylostoma in causing illness are such that he inclines to the view that the parasite has a considerable share in producing "beri-beri." In Cornwall the chief source of difficulty in this connexion is miner's phthisis, the symptoms of which are by no means always free from ambiguity. The effect of anthelmintic treatment is the most useful test.

### METHODS OF DETECTING EGGS IN FÆCES.

The difficulties of diagnosis are, however, considerable when infection is slight and no obvious anæmia is present. Accurate examination of the blood by the Haldane-Gowers hæmoglobinometer may be of assistance. With apparently healthy adult males any reading below 85 per cent. should excite suspicion. As a rule, plenty of eggs will be found in the fæces of even slightly anæmic cases and in many of those who have their full quantum of hæmoglobin. If few worms are present the discovery of eggs may be very difficult. Such a condition occurs especially in persons who have received specific treatment and from whom it is desired to expel absolutely every worm. In the ordinary way fæces are examined microscopically for eggs by smearing up a small piece, with the addition of water if necessary, into a sufficiently thin film on a glass slide. In the cases we are considering eggs will be found in such a preparation only by luck, and many infected stools will be passed as normal. Most of the fine mud can be removed by emulsifying a piece of fæces of the size of a nut and vigorously shaking up with water in a test-tube three-parts full. After standing for ten minutes all the eggs have fallen to the bottom and most of the supernatant fluid can be poured off. By repeating this process three or four times any eggs present can be obtained mixed only with the larger fragments, and the chance of finding them is very much better. Still further separation can be effected, as in Bass's method,[3] by taking advantage of the specific gravity of the eggs (about 1100). By washing with a solution of calcium chloride of specific gravity 1050 (12 per cent. hydrated salt) two or three times after washing with water, a good deal of light material can be got rid of, and by subsequently adding calcium chloride of specific gravity 1250 (55 per cent.) the eggs can be floated to the top and so separated from the crystals and heavy débris. Centrifugalisation saves time. Thus in one series of 315, 79 (25 per cent.) infections were found by direct examination and 38 more (12 per cent.) after washing.

The most accurate method of finding a few eggs appears to be cultivation and discovery of the larvæ. A convenient method of procedure is as follows. In the bottom of an ordinary 4 in. Petri dish make a pile of circular pieces of blotting paper about 2½ in. wide and ¼ in. high. Fill the dish with water nearly up to the level of the top of the papers and cover the island of paper with a thick layer of the fæces; incubate at 30°–36° C. for from five to seven days. When the larvæ hatch they swim away from the fæces into the water, which remains almost clear, and by centrifugalisation two or three can be found without much difficulty.

At the International Congress on Industrial Diseases held at Brussels in September, 1910, Bruns, who is in charge of the laboratory work in connexion with ankylostomiasis in the Westphalian coal-field, stated that of men with slight infections only 40 per cent. were diagnosed by direct microscopic examination, 55 per cent. by microscopic examination after gravity separation of the eggs, and 99 per cent. by the method of culture. This means that of every 99 men found infected by the culture method only 55 were diagnosed by microscopical examination, and that with every 99 positive by culture one case occurred which was negative to culture and positive to microscopic examination. There is no evidence to show how many cases of infection were not revealed by any of the methods. It is well known that some samples of stools are so noisome that the eggs will not hatch in them, so that the culture method cannot be regarded as infallible, though it is undoubtedly the best process available under all circumstances.

Other sources of error arise from the fact that the stools of an infected person may contain no eggs. It has already been pointed out that in experimental infection a period of from seven to ten weeks elapses after larvæ have entered the body before eggs are found in the stools.[4] Taking the shorter period as that which would most probably apply to large natural infections, there is therefore a considerable time after infection when examination of the fæces will necessarily prove negative. Eggs will also be absent if only male worms are present in the bowel;[5] it is inconceivable that under these circumstances enough worms should be present to cause any material illness, and such individuals are of course innocuous to others. It is also a matter of fairly common experience that eggs may not be found for a few days after anthelmintic treatment, but may reappear a week or two later. It is possible to explain these cases by an assumption that the eggs which ultimately appear have been laid by worms which were not fully developed and had not reached the intestine when treatment was administered. But in many instances so recent a reinfection can be excluded with considerable certainty, leaving only the usual and reasonable explanation that the shock of anthelmintic drugs temporarily paralyses oviposition.

Another source of failure to find eggs in the fæces produced for examination by an individual suspected of infection has been introduced along with schemes of compulsory examination and treatment which have for their object the

[4] Lambinet (Deutsche Medizinische Wochenschrift, 1904, p. 1848) showed that with *Ankylostoma caninum* in dogs the interval is only three weeks. Is the rate of development of the parasite proportional to the rate of metabolism (duration of life) of its host?
[5] A single male ascaris is not infrequently found post mortem.

exclusion of infected persons from certain places—e.g., the underground workings of a mine. If such procedures prove objectionable—as in fact they do—it is obvious that fæces which contain no ankylostoma eggs are likely to become an article of commerce, and it has actually occurred in the coal-fields of Belgium and Westphalia that infected workmen have presented for examination stools which were passed by somebody else. Hence policemen were set to supervise the personal production of samples for examination.

While, therefore, in many cases the diagnosis is simple enough, there are a good many circumstances which render the examination of fæces fallacious. These are especially frequent when infections are relatively slight and become of considerable practical importance when it is sought to establish some system of quarantine.

### EOSINOPHILIA.

The only point on which a diagnosis might be made in the first two or three weeks after infection is the skin eruption which marks the entrance of the larvæ. In characteristic cases and under conditions of exposure to infection a diagnosis might well be based on this alone, sufficiently positive, at any rate, to justify precautionary measures of quarantine. During the next four or five weeks examination of the blood may be of the greatest assistance. Most cases of ankylostoma infection show a considerable increase in eosinophile leucocytes in the circulating blood, and this increase is definitely perceptible about three weeks after infection. The following table shows the results of blood examinations made after experimental infections by the skin (Dr. Leathes) and by the mouth (myself):—

| *Skin Infection.* | | *Mouth Infection.* | |
|---|---|---|---|
| Days after infection. | Eosinophiles per cent. | Days after infection. | Eosinophiles per cent. |
| 0 | 2·0 | 0 | 3·4 |
| 14 | 7·4 | 8 | 2·6 |
| 21 | 3·0 | 14 | 10·0 |
| 27 | 14·4 | 36 | 24·0 |
| 43 | 13·4 | 41 | 33·6 |
| 44 | 20·8 | 48 | 40·4 |
| 48 | 35·6 | 55 | Eggs found. |
| 50 | Eggs found. | | |
| 52 | 44·8 | | |

In neither case was the slightest illness produced beyond the most trivial abdominal discomfort. Eggs were very few and far between, and it was only by prolonged examination of thoroughly concentrated samples that they were found at all. Indeed, in my own case daily examinations gave negative results about two days out of three, and both cases would, I am sure, have been, except by accident, passed as free from infection after examination of the ordinary film of unwashed fæces. It will be seen that by a fortnight or three weeks after infection the blood was obviously abnormal; eggs were not found till more than seven weeks had elapsed. Bruns and Müller[6] after experimental skin infection found 5 per cent. eosinophiles after three weeks, 10 per cent. after four weeks, and 25 per cent. after five weeks, eggs being found on the fifty-third day.

The facts which have been ascertained with regard to the general correlation of an eosinophilia with ankylostoma infection are as follows. Of 148 infected men in Cornwall (*A. duodenale*) the percentage of eosinophiles in a differential count of 500 leucocytes on a stained blood film varied between 3 and 73 per cent.: 5 had less than 5 per cent., 4 between 5 and 7 per cent., and 139 showed more than 8 per cent., of whom 123 had more than 10 per cent. and 49 more than 20 per cent.; the average of the whole number was 18·2 per cent. Experience shows that anything over 8 per cent. can be called a definite eosinophilia, figures between 5 and 8 per cent. being suspicious, but not necessarily abnormal. The most marked reaction seems to occur in young people who have been only recently infected and may not have become anæmic at all.

| No. | Age. | History. | Hæmoglobin. | Leucocytes. | Eosinophiles. | |
|---|---|---|---|---|---|---|
| | | | Per cent. | Per mm.³ | Per cent. | Per mm.³ |
| 1 | 23 | 1 month. | 80 | 56,000 | 66·2 | 37,000 |
| 2 | 18 | 6 months. | 98 | 20,600 | 56·2 | 11,500 |
| 3 | 17 | 6 ,, | 50 | 44,000 | 72·7 | 32,000 |

[6] Münchener Medicinische Wochenschrift, vol. lii., 1905, p. 1484.

In such cases there is a veritable eosinophile leucocytosis comparable to that which occurs in trichinosis. In cases of longer standing the number of eosinophiles may be much less, and in cases which have reached a severe degree of anæmia may be even less than normal. No marked examples of this were observed in Cornwall, but the careful work of Ashford with *A. americanum* shows clearly that the responsivity of the marrow may be depressed or almost destroyed by long-continued severe anæmia. Thus in one series[7] 21 per cent. had less than 5 per cent., and only 61 per cent. more than 8 per cent., all the patients having less than 50 per cent. hæmoglobin. In another series of severely anæmic cases 40 per cent. had less than 8 per cent. eosinophiles when first seen. An absence of eosinophilia was found in Porto Rico to indicate a bad prognosis. Dealing with men who were not anæmic, Bruns[8] in Westphalia, with *A. duodenale*, found 8 per cent. with less than 5 per cent. eosinophiles and 84 per per cent. with more than 8 per cent., the corresponding figures for Cornwall being 3 per cent. and 94 per cent., though the two series are not directly comparable since in Westphalia the men under examination had been treated on one or more occasions. In Belgian coalminers, Herman and Dascotte[9] found less than 5 per cent. in 18 per cent. of 200 cases, and over 8 per cent. in 65 per cent. Unless the reaction to *A. americanum* is altogether different from that with *A. duodenale*—and the Porto Rico results are against this supposition, the vast majority of worms there being *A. americanum*—the blood-counts of Dock and Bass[10] are inexplicable. In 693 infected persons the count gave less than 5 per cent. in 481 (69 per cent.), the average being 4·1 per cent. Most of the cases were very mild.

The effect of treatment on the eosinophilia is very irregular. In the majority of cases, starting with a marked eosinophilia, the leucocytes gradually come to normal or thereabouts as the worms are expelled and the patient recovers. In very anæmic persons treatment may produce an eosinophilia which subsequently declines. In others, again, the eosinophilia may persist long after all worms have been destroyed. The following examples illustrate these points:—

| CASE I. | | | CASE II. | | | CASE III. | | |
|---|---|---|---|---|---|---|---|---|
| Date. | Hb. %. | Eosin. %. | Date. | Hb. %. | Eosin. %. | Date. | Hb. %. | Eosin. %. |

| Aug. 15th ... | 101 | 8·8 | Aug. 4th... | 90 | 2·2 | | | |

The third case shows particularly well how a marked enosinophilia may persist for at least two years after expulsion of the worms. The man had been dosed several times, and repeated search failed to reveal any eggs. We examined also in Cornwall four men who had given up underground work some years previously, and in whose stools no eggs could be found; their blood showed an eosinophilia of from 11 to 22 per cent.

Eosinophilia, therefore, is of no value in gauging the results of treatment or in ascertaining whether the worms have died out from an infected person. But under certain circumstances it may be of considerable help in diagnosis. It is, in the first place, obvious that other causes of eosinophilia must be absent, or at any rate infrequent. The causes of eosinophilia other than ankylostoma are: (1) true paroxysmal asthma; (2) pemphigus and the bullous eruptions of the dermatitis herpetiformis group; (3) other animal parasites—i.e., bilharzia, ascaris, oxyuris, trichina, filaria, and tænia.[11] Of these bilharzia and trichina alone give a marked eosinophilia with anything like the regularity seen in ankylostoma infection. Trichocephalus,[12] by far the commonest

[9] Bulletin de l'Académie Royale de Médecine de Belgique, vol. xxii., 1908, p. 75.
[10] Hookworm Disease, 1900, p. 180.
[11] Journal of Hygiene, vol. iv., 1904, p. 466.
[12] Ibid., vol. v., 1905, p. 278.

intestinal worm in this country, gives no definite reaction. The data recently collected by Schloss [13] show the frequency with which worm infections cause eosinophilia in children in the United States :—

| Worm. | Number of cases. | Eosinophilia. | | Highest eosin. count. |
|---|---|---|---|---|
| | | Over 8%. | Over 10%. | |
| Trichocephalus... ... ... | 31 | 0 | 0 | 6·4 |
| Oxyuris ... ... ... ... | 23 | 5 | 3 | 14·0 |
| Ascaris... ... ... ... ... | 6 | 2 | 0 | 9·2 |
| Hymenolepis ... ... ... | 20 | 7 | 4 | 22·6 |
| Tænia saginata ... ... | 3 | 2 | 1 | 13·2 |
| Total ... ... ... ... | 83 | 16=19% | 8=10% | — |

In 83 infections, therefore, only 16 (19 per cent.) had a definite eosinophilia. Blood examinations are, however, not much use for diagnostic purposes in places such as the tropics, where worms are very prevalent, except in so far that the absence of an eosinophilia in a reasonably robust subject may be taken to exclude ankylostoma infection with a fair degree of certainty. But in this country the method is of great practical utility. Worm infections are not common, and as a matter of ascertained fact eosinophilia is distinctly rare in the general population. To investigate this point blood films were obtained from 158 underground workers in uninfected coal, lead, and tin mines, and from surface workers at Dolcoath. Their differential counts contrasted with those of Cornish miners infected with ankylostoma were as follows :—

| Percentage of eosinophiles. | Infected miners. | | Non-infected miners. | |
|---|---|---|---|---|
| Less than 1 per cent. ..... | 0 | | 29 | |
| 1 per cent. ..... | 0 | | 49 | |
| 2 ,, ..... | 0 | 3·4% | 32 | 91·2% |
| 3 ,, ..... | 4 | | 23 | |
| 4 ,, ..... | 1 | | 11 | |
| 5 ,, ..... | 2 | | 5 | |
| 6 ,, ..... | 1 | 2·7% | 5 | 7·0% |
| 7 ,, ..... | 1 | | 1 | |
| 8 ,, ..... | 7 | | 1 | |
| 9 ,, ..... | 9 | | 0 | |
| 10 ,, ..... | 40 | | 0 | |
| 15 ,, ..... | 34 | 93·9% | 0 | 1·8% |
| 20 ,, ..... | 22 | | 1 | |
| 25 ,, ..... | 8 | | 1 | |
| More than 30% ..... | 19 | | 0 | |
| Total examined ..... | 148 | | 158 | |
| Average eosinophiles % ..... | 18·2 | | 2·5 | |

The figures for infected miners suggest that any figure above 8 per cent. may be regarded as indicative of infection. Of the three cases above this figure among the men not infected with ankylostoma, one (8·4 per cent.) had trichocephalus and oxyuris, the other two (23·8 and 25·6 per cent.) trichocephalus and ascaris; all three came from Levant mine, where worm infections are very common.

In holding an inquisition for ankylostoma this method of examination is therefore very useful. It is easy to obtain blood films from the men, and any question of fraud is excluded. I do not know what sort of response one would obtain if one descended on some mine in this country where the terrors of ankylostoma were unfamiliar, and asked 100 men to produce samples of fæces for examination, but I imagine that at any rate a great deal of time would be consumed before such an examination was complete. The same number of men can be examined by the blood film method in a few hours. It is quite unnecessary to count all the films; after a little practice the obviously negative and positive cases can be separated by a short inspection of the slide. As a further proof of the pudding, I give the results of a search recently conducted, in conjunction with Cadman, in likely places for ankylostoma. Films were obtained from a good proportion of men working underground in hot and wet mines; samples of fæces were subsequently obtained from any cases showing more than 8 per cent. eosinophiles.

[13] American Journal of the Medical Sciences, vol. cxxxix., 1910, p. 675.

In all, then, of 619 men, four showed an eosinophilia; on further inquiry none of these had ankylostoma. The method is particularly useful in an inquiry for latent infection, since the reaction is best marked in the young and lusty who are not anæmic—the people, that is, who are least liable to be suspected of infection; and, as pointed out above, it may be very well marked in extremely slight infections, appearing in a recognisable form after infection several weeks before there is any chance of finding eggs in the stools. It is possible that precipitin and Bordet-Gengou reactions may prove of service in diagnosis as they have in other worm infections.

## THE CONDITIONS WHICH DETERMINE THE PREVALENCE OF ANKYLOSTOMA INFECTION.

One has learned so much in recent years about the direct transmission of pathogenic parasites from host to host, that one recognises something exceptional in the case of ankylostoma, where the chief circumstances which influence development outside the body are those which condition the prevalence of infection in man. Some parasites, such as the gonococcus or spirochæta pallida, have no life outside the bodies of their special host; others, as trypanosomes, malaria organisms, and cestode worms, oscillate between two different animal hosts; others, again, though apparently capable of no inconsiderable saprophytic life, like the diphtheria bacillus, the typhoid bacillus, or the meningococcus, depend in the main on living animals for the continuance of their existence; organisms which have an active, proliferative, saprophytic life, such as the tetanus bacillus, are now known to be in the minority among the infective agents of important human diseases. In ankylostoma, on the other hand—and the same is, of course, true of the other common nematode parasites ascaris and trichocephalus—the saprophytic phase is of fundamental importance. Since the eggs cannot develop during the parasitic phase, since they cannot again enter the parasitic phase till they have become definitive ("encapsuled") larvæ, and since the larvæ cannot become sexual and multiply without changing the saprophytic for the parasitic phase, it is obvious that the conditions which determine, in the saprophytic phase, the development of the eggs into larvæ are as fundamental to the propagation of ankylostoma as is the existence of a host in which a multiplication of individuals takes place. Its existence in nature is to ankylostoma what the mosquito is to the malarial parasite, or *Limnæa truncatula* to the liver fluke. The influence of various physical circumstances on the life of ankylostoma may be grouped under the following heads :—

1. *Oxygen.*—A free supply of oxygen is necessary for the growth of the embryo, and in its absence the eggs do not hatch and die in a few days. Eggs, therefore, cannot possibly hatch in the intestine. They will very rarely hatch if they are covered in an open dish with a layer of ordinary tap water about an inch deep, though this contains oxygen to begin with and does not offer any great obstacle to diffusion. Even if the water is stirred by bubbling hydrogen through it they seldom hatch, though a fair proportion develop if a good stream of air is kept passing through the liquid. Eggs, therefore, will not hatch if fæces are passed into a good volume of water, nor will those in the interior of fæcal masses make much progress. The eggs are not, however, killed by deprivation of oxygen in less than about 10 days; at low temperatures they would probably survive longer. The young larvæ, as might be expected, also require a free supply of oxygen while they are growing rapidly, though they thrive well in water, but when they become full grown and encapsuled they develop some of the remarkable anaerobic capacities shown by adult intestinal worms, and apparently derive the energy required for their very active movements by fermentation rather than by direct oxidation, as shown by

Weinland in his study of the metabolism of adult ascaris.[14] At this stage they will live for at least two or three weeks, wriggling about all the time, in hydrogen or nitrogen at room temperature; in parallel experiments at 37° C. they died in about 24 hours.

2. *Moisture.*—At any stage of development from egg to encapsuled larvæ desiccation at ordinary temperature is very soon fatal. Hence some degree of wetness in the place where infected fæces are deposited is necessary for the development of infectivity. Ankylostomiasis never prevails very extensively in dry places. In this connexion it should be remembered that really dry districts are uninhabitable, and that the holes and corners in which fæces are apt to be deposited in nature are liable from their situation to be rather specially damp, if only because they are sheltered and evaporation hindered. The influence of vegetation in preventing the surface of the earth from drying is of considerable importance. Thus in Porto Rico the sugar fields are not nearly so heavily infected as coffee and banana plantations. The former are ploughed up every year and the surface is freely exposed to the sun after the crop is harvested, while the coffee bush itself produces shade and in its turn is always shaded by some other tree. The ground beneath banana plants is densely shaded, and the mass of decomposing leaves and stalks remains wet for a long time after rain, and forms an ideal medium for the protection of the larvæ.

In mines the influence of moisture is equally well marked. The rise and progress of ankylostoma infection to the proportions of a serious epidemic in the Westphalian coal pits followed the introduction of watering the roads to prevent dust explosions. The following figures show how the prevalence of infection increased, watering being begun in the last six months of 1899:—

| Year. | Number of collieries infected. | Number of cases reported. | Cases per 10,000 miners working. |
|---|---|---|---|
| 1896 ..... | 15 ..... | 107 ..... | 6·4 |
| 1897 ..... | 31 ..... | 113 ..... | 6·2 |
| 1898 ..... | 23 ..... | 99 ..... | 4·9 |
| 1899 ..... | 26 ..... | 94 ..... | 4·4 |
| 1900 ..... | 40 ..... | 275 ..... | 11·7 |
| 1901 ..... | 63 ..... | 1030 ..... | 40·6 |
| 1902 ..... | 66 ..... | 1355 ..... | 52·9 |

Active measures against the disease were commenced at the end of 1902, when a careful survey revealed about 18,000 infected men (9·1 per cent.). The gold mines in South Africa are almost quite dry, and though about half the native labourers working underground are already infected when they first come to work there is no evidence that infection tends to spread, and there have been few, if any, cases of the white miners acquiring the disease there. In Cornwall all the mines are more or less wet, but those which have a considerable proportion of dry roads and galleries are among the less heavily infected. Many coal pits in this country are too dry for the development of the larvæ. The recognition of the importance of coal-dust in the causation and propagation of underground explosions may, however, lead to the introduction of water sprinkling, with the result that in this respect conditions may become favourable. The alternative plan of having "dustless zones" on the roads is much to be preferred from the present standpoint.

3. *Temperature.*—The effect of cold is not altogether certain. My own experience is that the eggs die if kept for a few days near freezing temperature, and Stiles and Bruns[15] obtained the same result. Bruns also found that freezing kills the larvæ in an hour or two. Oliver,[16] on the other hand, finds that infected fæces may be frozen and the eggs still remain capable of hatching, and that larvæ may be buried in snow for six days without necessarily losing their vitality. The lethal effects of high temperatures on eggs and larvæ are well shown in Bruns's experiments. (Next table.)

Fæces in nature can hardly become heated as high as 48° C. (118° F.) unless they are at the same time being dried. It may occasionally happen that so hot a place occurs underground with an atmosphere saturated with moisture; such would be of no practical importance since men could not work there.

*Effect of Heat on Eggs.*

| Temperature. | Duration of heating in minutes. | | | | | |
|---|---|---|---|---|---|---|
| | 1 | 2 | 3 | 5 | 10 | 15 |
| 47° Centigrade. | + | + | + | + | + | + |
| 48° ,, | + | + | + | + | + | + |
| 49° ,, | + | + | + | + | − | − |
| 50° ,, | + | + | + | − | − | − |
| 51° ,, | + | + | + | − | − | − |
| 52° ,, | + | + | − | − | − | − |

| 51° ,, ... ,, | 5 ,, | 56° ,, ... ,, | 1 ,, |
| 52° ,, ... ,, | 3 ,, | 60° ,, ... ,, | 1 ,, |

Experiments in which the eggs and larvæ are kept continually at the same temperature show, however, that a less degree of heat is distinctly detrimental. At 36°–38° C. (97°–100° F.) the eggs often die without hatching; a few larvæ generally hatch out in about 24 hours and as a rule rapidly die away, only a very few surviving to the infective stage. Encapsuled larvæ which have been reared at a lower temperature have, in my experience, always died in a few days at 37° C., though they will live under the same conditions at room temperature for more than a year. The further development which they undergo when they gain entrance to the human body must be associated with a change in their temperature relations. Conditions probably seldom occur in nature which would make these facts of great practical importance. If fæces are dried the eggs and larvæ are killed in any case; if they remain moist their temperature will be reduced by evaporation if the air is not too humid. There is no inhabited part of the world where a temperature approaching 98° F. prevails for any length of time associated with a high relative humidity; such a combination would hardly be compatible with human life.[17] In mines restricted areas of the workings may be as hot and wet, but this is very uncommon. In Levant Mine in Cornwall some of the deeper galleries have a temperature of 93° F. with saturated air. At Schamrock Mine, in Westphalia, Meyer found that 15 per cent. of men working at about 20° C. (68° F.) were infected; 56 per cent. between 20° and 25° C. (68°–77° F.) and only 28 per cent. between 25° and 29° C. (77°–84° F.); but it is difficult to be certain that all the other circumstances were identical.

At the lower end of the scale the development of ankylostoma is also definitely limited by temperature. I have twice succeeded in hatching eggs and growing the larvæ to the encapsuled stage in an incubator in which the temperature was generally 15·9° C. (60·6° F.) and never exceeded 17° C. (62·5° F.), but such experiments do not always succeed either as regards hatching of eggs or development of larvæ. The lowest point at which really free and full development of the majority of eggs is to be expected is placed by Bruns at 20° C. (68° F.), and this is in accordance with my own experience. The encapsuled larvæ live very well at 15° C.

The widest possible range of temperature is therefore 15° C. (59° F.) to 38° C. (100° F.), but the range which is suitable for the great majority of eggs to hatch and larvæ to develop and continue to live when they have reached the encapsuled stage is restricted to the interval between about 20° C. (68° F.) and about 32° C. (90° F.).

As might be expected, temperature has a marked influence on the rate of development. At 35° C. (95° F.) free larvæ

[17] Journal of Hygiene, vol. v., 1905, p. 494; Journal of Pathology, vol. xiii., 1909, p. 62.

may appear in 24 hours and encapsuled larvæ in four days; at 16° C. (61° F.) the eggs take three to seven days to hatch and encapsuled larvæ may not be present for a fortnight. Taking all the circumstances into consideration we should suppose that the optimum temperature for the saprophytic phase of ankylostoma is somewhere about 27° C. (80° F.).

These experimental observations are fully in accordance with the observed epidemiological facts. The annual isotherms of 16° C. (61° F.) mark fairly accurately the limits of the distribution of infection of an epidemic degree about the world. Thus the disease is prevalent in the Southern but not in Northern United States, in Spain and Italy but not in France or Germany, in Queensland but not in Victoria. For obvious reasons the correspondence cannot be expected to be very exact, but we should expect that infection might be extensive anywhere where the mean annual temperature was over 60° F., while in cooler climates nothing beyond sporadic cases would occur. The following table shows the mean monthly and annual temperatures for a number of places in which infection does and does not occur. Thus the West Indies (represented by Trinidad), Assam (Calcutta), and the Southern States (Georgia) are all notorious foci; in Queensland (Brisbane) there is widespread infection, and a considerable amount of ankylostomiasis occurs in Italy[18] (Naples). In Victoria (Melbourne), on the other hand, the disease is not known, nor does it occur in the Northern States (Chicago), nor among the general population in France, Germany, or England.

It is pretty clear, then, that the disease does not gain a foothold under circumstances of temperature which experiment has shown to be not incompatible with the development of infective larvæ from the egg. Thus in this country it appears from the Greenwich Records for the 50 years 1841–1890, that the mean daily temperature is, on the average, over 60° F. on 71 days in each year, the mean maximum over 60° F. on 162 days, and over 70° F. on 85 days; the temperature exceeds 70° F. on 85 days, 80° F. on 14 days, and 90° F. on one day. In July, 1859, the thermometer rose above 80° F. on 21 days, and in July, 1868, on 20 days. As a matter of fact, if one leaves infected fæces in the open air in London in the summer one may after a time find encapsuled larvæ in them, though not in all samples. Oliver has observed the same thing in Newcastle. One would not expect to find ankylostoma rampant in this country owing to the effective control of fæcal contamination, but experience shows definitely that infection equally fails to spread in uncivilised countries of like climate. But such spread is not impossible. A certain number of cases have been known for many years to arise in the brickmakers[19] in the Cologne district, and there is at least one case where infection was acquired in New York by a boy who played in his father's brickyard in which were workmen who had brought the worm from elsewhere.[20] There does not seem to be any known infection in the neighbourhood of Chicago, although the summer there is very hot, and during the two months in which the mean monthly temperature is over 70° F. eggs would readily hatch and quickly develop into infective larvæ.

The only localities in North-Western Europe in which ankylostoma can thrive and make any headway are the underground workings of mines. Most mines are warm, and many hot, from a variety of causes. As pointed out by Haldane,[21] these high underground temperatures are due, in the first place, to the natural temperature of the earth, which increases with the depth from the surface by about 1° F. for every 60 ft. Thus the mean annual temperature on the surface in Cornwall is about 50° F., and the natural temperature of the rock at 1800 ft. is about 80°, and at the greatest depth at present reached in Dolcoath mine (500 fathoms = 3000 ft.) about 100°. As far as this source of heat is concerned the mines will go on getting hotter as they get deeper. A certain amount of heat is also produced by the men, animals, lights, and explosives underground, and the incoming air is warmed by compression as it comes down the downcast shaft. The most important source of the generation of heat underground is, however, the oxidation of the minerals as they are exposed to the air. There are good reasons for thinking that the chief process of this kind going on, both in coal and metalliferous mines, is the oxidation of iron pyrites. According to some, heat is also produced by the shearing and straining of the strata when they are disturbed and are capable, as in coal-pits, of a certain range of movement, but it is doubtful whether this possible source of heat is of any quantitative importance. On the other hand, the temperatures which would in this way be reached are actually diminished to a greater or less degree by the cooling effect of the ventilating current of air which operates partly by taking up heat from the rock and, which is more important, by evaporating water out of the workings. Hence the actual temperature of any place underground will, depth and other conditions being equal, depend largely on the volume of ventilation; the downcast shafts and intake roads will be cooler than the upcast shafts and return roads, and dead ends without any through ventilation will be especially hot. A mine may also be cooled a good deal by the percolation through the strata of surface water, which is ultimately pumped out from the bottom.

In considering the effect of underground temperatures on the propagation of ankylostoma, it is important to note that there is relatively little variation at different seasons of the year, except near the intake of fresh air.

In Cornish mines considerable areas of the underground workings are over 70° F. In Dolcoath mine, for instance, a good deal of the deeper galleries have a temperature between 75 and 80°, and in places where fresh rock is being opened up by tunnelling temperatures of 98° or thereabouts are not uncommon by reason of the high natural temperature of the virgin rock and the absence of any effective ventilation. In Levant mine, where the ventilation is very imperfect, the temperature where much of the work is now being done is over 80°, and in some places as high as 90°. In other mines, however, which are not so deep and better ventilated temperatures are much lower (60–70°). The temperature of coalpits in this country varies in the same way, and it is impossible to make any general statement on the point, if only because the temperature varies so much in different parts of the same pit. There is, however, no doubt that as far as temperature alone is concerned there are many places in British coal-pits where ankylostoma would get on very well. In their exhaustive report[22] on the ventilation of coal-mines Professor John Cadman and Mr. E. B. Whalley incidentally give a number of data relating to 43 collieries which were not selected as being particularly hot. In 30 temperatures of over 70° F. were observed, in 12 of which the thermometer recorded over 80°, and in 2 more than 90°. In another series of 20 collieries in North Staffordshire, temperatures over 70° were observed in 15, and over 80° in 5. In Westphalia in about two-thirds of the collieries the temperature is less than 70°.

[18] Of 1200 patients in the hospital at Pavia in 1909 Marti found 76 cases of ankylostomiasis.

[19] The temperature in such places may well be a good deal above the screen records in the neighbourhood.

[20] W. R. Stone: Medical News, vol. lxxxii., 1903, p. 680. A second case is recorded by H. Brooks, Medical Record, vol. lxxvii., 1910, p. 191.

[21] Report on the Health of Cornish Miners, Parliamentary Paper, Cd. 2091 (1904), pp. 93, ff.

[22] Royal Commission on Mines, Cd. 4551, 1909.

there is, as I am informed by Professor Cadman, a strong local feeling on the subject which has a most beneficial effect. The actual stink and nuisance is much diminished by the deodorising effect of the coal, and in searching for fæcal deposits in coal-pits one has to rely mostly on sight. In any case the bulk of fæces subsisting in exposed situations in a coal-pit at any moment will always be less than in a metalliferous mine owing to the relatively transitory nature of the exposed surface. At the working face the coal is excavated and removed very much more quickly in tons per man than is the granite or other hard rock which forms the matrix of most metalliferous deposits. As the coal is taken out, the roof is allowed to fall in and fill up the gap, and the men seem to make it a habit to defæcate in the "goaf" or "gob" in which the waste débris is stowed, and which will very shortly be shut off for ever from any further contact with human beings. Even the main roads which lead from the shafts to the working face are constantly being renewed; the floor tends to rise and the roof to fall, so that the surface has to be frequently cleaned up. In the hard rock of metalliferous mines, on the other hand, progress is much slower at the site of actual excavation, and the roads are practically permanent.[51] Hence fæces tend to accumulate as they do in communities of fixed abode; coal-miners enjoy some of the advantages of a nomadic people.

### Insanitary Conditions and Spread of Ankylostoma Infection.

One of the most striking examples of the influence of neglect of sanitary precautions on the spread of ankylostoma infection is afforded by the prevalence of the disease in the Southern United States. It is clear from the comprehensive observations of Stiles and many others[52] that ankylostomiasis is one of the most potent causes of chronic ill-health and inefficiency among the agricultural population in these parts. In the large cities it is limited to imported cases and those infected away from home. What is surprising to us is that the farming class should be so grossly filthy in their habits. Dock and Bass[53] state that in the country there are few privies, and such as there are are only used for shelter and convenience. The safe disposal of fæces is not considered and, owing to defective construction, pigs and fowls can root and scratch about among them and so scatter eggs around. They show by direct experiment that ankylostoma eggs can be fed to chickens and larvæ readily hatched from the eggs when they are subsequently p'ssed by the fowls. In this way infection might be disseminated very widely.[54] During wet weather fæces are liable to be washed out of the primitive shelters, which are, if possible, placed on a slope to keep them as dry as may be. About three-quarters of the rural population have not got a privy even of this inefficient sort. Any more or less retired place near the house is used by the adults, while of the rest of the family they say, "It is often possible to determine the number of children in a family by the number of piles of fæces in the backyard. ..... In small towns, where many country people come to market, there is often some near-by thicket, or gully, or barnyard to which the country people go when they get 'in a tight,' in preference to privies, to which they are unaccustomed even if they are available. The country people are more or less infected, and they thus convert these resorts into veritable hotbeds of hookworm larvæ. We remember such a 'gully' near a country town, and with our present knowledge we now see ample explanation of the ground itch and anæmia among many of the town boys, who often went barefoot in warm weather. The most favoured parts of the 'gully' were so much used for this purpose that there often seemed to be no more room. Many of the country schools are not provided with any sort of a privy." A lurid picture of the habits of a white population which is said to represent the purest breed of English that still survives. In Georgia, Wells[55] found about 24 per cent. of the total white population outside towns infected; of 280 school children 137, or 49 per cent., had the worm. Among university students from the Southern States 37, 42, and 37 per cent. have been found infected in different inquiries; among army recruits 60 and 88 per cent.; half the white population of Mississippi are infected, and in the cotton-mills 13 per cent. are ill enough to hinder their work.

### Conditions Favouring Infection by the Skin.

Besides the physical circumstances which prevail and the efficacy with which the disposal of fæces is carried out, a third group of circumstances which may materially influence the prevalence of ankylostoma infection is found in the degree to which the human skin is immediately accessible to the larvæ. Wearing boots is in many circumstances obviously a pretty complete protection, and to this no doubt Europeans owe their almost complete immunity when living in places in the tropics where the barefooted natives are infected to a man. Infection on the feet is doubtless the commonest mode of attack, and it is on the feet that "ground itch" and "mazamorra" characteristically occur. Boots are, of course, no great protection when the nature of the occupation brings the hands and arms into intimate contact with infected earth. Hence the special prevalence of infection among agriculturists in the tropics, and among brickmakers and miners in North-Western Europe. Cornish miners wear boots which are often leaky, thin canvas trousers, and some sort of vest or shirt, together with a hard hat. In the hotter places they usually work stripped to the waist. "Bunches" are somewhat rare on the feet, occurring most commonly on the arms and legs. It is obvious from looking at the men that they are liable to be smeared with mud all over their bodies while doing their work in the cramped quarters which they have underground. Hence one is not surprised at the occurrence of the skin lesions in any part. "Sat down on muddy stone last Thursday, and has bunches on left buttock which came out the same night," is a representative note.

Such are the conditions which determine the prevalence of ankylostoma infection. Three are of outstanding importance—moisture, temperature, and fæcal contamination of the soil, and to ensure the existence of the parasite in any place all three must be simultaneously favourable. In the tropics this coincidence is commonly found. In mines in North-Western Europe, on the other hand, infection is often rendered impossible because one of these three conditions is unfavourable. Fæcal contamination is, or at any rate has been, everywhere pretty extensive, and most mines of any size are in parts either hot enough *or* wet enough. But relatively few underground works are at the same time and place hot enough *and* wet enough to give the parasite a reasonably good opportunity. If conditions are not unfavourable, the intensity of prevalence, as measured by the proportion of persons exposed who are infected and the proportion of those who have a large enough infection to make them ill, will vary as the product, rather than as the sum, of the degree to which moisture, temperature, and fæcal contamination are coincidently suitable for the development of the increasing number of eggs which the soil receives as infection becomes more widespread and more intense among the human population. Thus, one may have every grade of prevalence, from the scattered cases which, as Iberer[56] has shown, occur among the general population in the south of Hungary to the universal infection subsisting in Porto Rico, just as in Cornish mines, which are rather cool and dry, only 10 per cent. of underground workers are infected and none are sick, while at least 95 per cent. harbour the worm in hot, wet workings and 5 per cent. are too ill to work.

BIRMINGHAM GENERAL DISPENSARY.—From the committee's report it appeared that the receipts for the year amounted to £11,004 8*s.*, and that after meeting all expenses there remained a balance in hand of £196 17*s.* 9*d.* The increase in subscriptions was £211 8*s.* and the expenditure showed a decrease of £604. The total number of patients admitted by ticket was 58,757, and the average cost of patients was 3*s.* 4·1*d.* During the year 3693 dental patients had been treated and emergency cases treated without tickets numbered 1760, bringing up the total number of patients to 64,210.

# MYOSITIS OSSIFICANS TRAUMATICA.[1]

BY RICKMAN J. GODLEE, M.S., F.R.C.S. ENG.,
PRESIDENT OF THE SURGICAL SECTION OF THE ROYAL SOCIETY OF MEDICINE; SURGEON-IN-ORDINARY TO H.M. THE KING; SURGEON TO UNIVERSITY COLLEGE HOSPITAL.

MORE than three years ago, on Dec. 6th, 1907, I saw a youth, aged 18 years, who a month before, on Nov. 9th, had been kicked on the front of the thigh at football. He continued to play for three minutes though in bad pain. Swelling occurred the same day and bruising came out later. He kept his bed for one day, then was about for two days, after which he rested for ten days, whilst the limb was fomented and afterwards painted with tincture of iodine. He was then allowed to walk a little and massage was applied. When I saw him there was apparent a very large oval swelling on the front of the lower half of the thigh. It was symmetrical and very hard, except just above the patella, where it fluctuated, and there was only slight pain on movement. I told him to leave it alone, and he returned to Oxford, where he did ordinary walking. In February, 1908, he tried football three times, but had to give it upon account of pain and stiffness. Otherwise it was all right till Feb. 26th, when it suddenly became stiff and hard again, and when I saw him on Feb. 28th it was in appearance much as when I saw him in December, except that it was now hard all over. It was perhaps slightly smaller, but still measured 5 in. from above down, and reached to 1¾ in. above the patella. It was obviously fixed to the bone, and I then had a skiagram taken, which shows a large dark shadow corresponding to the tumour, which, it will be seen, is even larger behind than in front, and there is a still more defined shadow of laminæ of what appears to be bone on the front of the femur; for the most part these are parallel with the shaft, but tail off at the upper part into layers which slant obliquely towards the bone.

On March 8th I saw the patient again with the late Mr. Clutton, who showed me three or four skiagrams of similar cases, and told me of two which had been operated upon (one by himself) in which the operation distinctly did harm. I was therefore fortified in my opinion to leave him alone, and after six months he had no further trouble.

I saw the patient again in March, 1910. The lump had almost gone. But another skiagram shows that there was then a distinct flake of bone on the front of the femur fading off above into the surface of the shaft, but ending below in a sharp spicule. He now pays no further attention to the thing at all.

One object of bringing this case before the section is to point out that a very large swelling may without treatment diminish so much in size as almost to disappear and cause no further trouble or inconvenience. It should be remembered that the shadow in the earlier skiagram does not necessarily show the amount of the bony deposit at that time, as it would probably be, like early callus, transparent to the X rays. This being the case, and the experience at all events of some surgeons having been that removal has actually done harm, I would urge the advisability of leaving these swellings alone until ample time has been allowed, at least a year, for the absorption of what may be called provisional callus. Even after this time I think that removal would only be justified if the mass were causing mechanical inconvenience and pain. It must be remembered that the operation is inflicting another traumatism upon a part which for some reason has shown a special tendency to the development of bone, and it cannot therefore be surprising if renewed activity of the process should follow.

To support this proposition I have searched some of our museums for specimens of bone showing the results of such injuries, but I find that they are not numerous. By a curious coincidence, whilst I was being told that we have nothing of the sort in the Anatomical Museum at University College, the beadle brought in a fine example which he wished to exchange for a normal femur. It will be seen that it occupies a part of the bone from which both vastus externus and crureus arise. It is sharply outlined, suggesting that the periosteum had been stripped up over a limited area. Its surface is firmly granular and rough, contrasting with that of the vertically ribbed highly polished normal bone. It ends, like all the specimens, in a free point below.

In the Museum of the Royal College of Surgeons there are two femurs, No. 1911 and No. 1911, both Hunterian, showing similar plates of bone. In that of St. Thomas's Hospital is one in the crureus, and at St. Bartholomew's Hospital are three admirable specimens which, by the kindness of the authorities, I am permitted to show and of which I produce photographs. Two of these are much like my own specimen, but one is particularly interesting because it corresponds almost exactly with one removed by Mr. P. M. Heath, which is now in the Museum of the University College Hospital Medical School. This case was described by Mr. Heath in the Transactions of the Clinical Section of the Royal Society of Medicine.[2] It shows a large mass of bone, not smooth, like most of the others, but raised into deep, rounded, vertical ridges, looking, it must be owned, like a deposit in the muscular fibres of the vastus or the crureus. I suggest that this is only an earlier condition of that which the other specimens show, and that in time it would have been, in great part, absorbed and have left the smooth rounded swelling to which I have drawn attention. We have had a transverse section made of Mr. Heath's specimen, and of this I show a microscopical section. It will be seen that the mass of bone is hollow. On its surface there is muscular tissue undergoing hyaline degeneration, the interstitial tissue of which is increased, and amongst the layers of which is blood pigment. Between this hollow plate and the front of the bone is a thick mass of grey gelatinous material rather like myxomatous tissue containing vessels scattered about in which are a few isolated groups of atrophied muscular fibres.

Naturally these cases would not come under the eye of the pathologist, and in the dissecting-room would not be of much interest to the anatomist. It is therefore interesting that Professor G. Elliot Smith tells me he did not come across any examples amongst the large number of prehistoric bones he examined in Nubia, and that none were furnished by the great haul of bones from the East-End plague-pits which found their way to University College.

So far, I have only referred to injuries to the femur, but a large number of cases of a similar process occurring in the neighbourhood of the elbow have been described, some in connexion with fractures, and others with simple dislocations. I show skiagrams of the elbow of a boy of 6 who broke his humerus in 1903. It was re-fractured on account of stiffness seven weeks later, but soon was as stiff as ever. Six months after the accident there was a bridge of bone uniting the front of the humerus to the coronoid process and absolutely locking the joint. This would be called a deposit in the brachialis anticus. I restored the joint to a fair degree of utility by removing it; but a later skiagram shows a considerable amount of fresh bone deposit after my operation.

A most elaborate paper on the subject by Mr. Robert Jones[3] records 17 cases of his own and over 140 by Cahier and Binnie. At that time Jones concluded that operative treatment was essential. It is therefore interesting that he should now write to me under date Feb. 28th, 1911: "Since writing the article I have come upon cases where the deposits, instead of increasing have decreased, and I am not now at all convinced of the value of operation. The simplest-looking mass in the bend of the elbow is a very difficult problem to negotiate operatively, and I have on more than one occasion wished I had left the whole thing alone."

Still it must be allowed that, in some of the elbow cases with complete locking, operation appears to be essential, and also that in some of the early operations on cases in the thigh, even if they are not, as I think, necessary, no harm has resulted. Such, for example, was the result in Mr. Heath's case, and in one other to which I must refer, because a careful examination was made of the parts removed.

Sir Frederic Eve described a case[4] apparently very much like Mr. Heath's, in which the bone was removed 11 weeks after the injury with good result. A microscopical examination showed atrophy or degeneration or disappearance of the muscle in the neighbourhood. But it is not clear that any sign of muscle was found in the thin layer of soft tissue which intervened between the bony mass and the femur.

[4] Transactions of the Clinical Society of London, vol. xxxii., p. 233.

The author agrees that injury to the periosteum is an essential part of the condition.

I come, then, lastly to the question of whether this condition should be called myositis and what is the evidence that it is due to inflammation of muscle. To me it seems more probable that the essential things are first an injury to the periosteum, and, secondly, an effusion of blood; and that the injury to muscle and the inclusion of muscular fibres in the callus are, so to speak, accidental, though it no doubt governs the shape and position of the new mass of bone. In other words, I think it is more analogous to what occurs when periosteum is stripped off in such operations as excision of the elbow, or in the cephalhæmatomata of infants, in which it is easy to demonstrate true bone at the margins of the clot, or to the formation of provisional callus in simple fractures. I know it is suggested that the process is the same as that which causes the "rider's bone" or the "exercise bone," but it appears to me to be a very different one. In these there is no evidence of injury to the periosteum unless it be suggested that they are to be compared with the cases described by Sir James Paget where necrosis occurred at the insertion of a strained muscle. The strongest argument for the myositis theory is afforded by some recorded cases where the new bone was not in actual contact with that which had received the injury.

If the essential factor, then, is injury to the periosteum it is surely a pity that the name which has been applied to this condition should confuse our ideas of myositis, and especially of myositis ossificans, about which it must be allowed our present notions are quite vague enough.

Wimpole-street, W.

## ON TRAUMATIC MYOSITIS OSSIFICANS.[1]

BY G. H. MAKINS, C.B., F.R.C.S. ENG.,
SURGEON TO ST. THOMAS'S HOSPITAL.

IN a paper by Schultz dealing with the occurrence of traumatic myositis ossificans in the German army during a period extending over ten years the respectable number of 233 cases has been collated, showing that the affection is more frequent than is commonly supposed. I take it that the frequency depends upon the fact that soldiers are carefully examined for any defects in physical efficiency, while amongst the civil workers the minor degrees of such a condition as this are often overlooked. Amongst Schultz's cases only three are noted as affecting other muscles than the quadriceps extensor femoris and the brachialis anticus. The exceptions are two instances of ossification of the masseter following horse kicks and one of the pectoralis major due to a blow during bayonet exercise. In a paper by Ewald examples are quoted of ossification of the deltoid, triceps, biceps, adductor magnus, and subclavius following accidental injuries, also Horvath's remarkable case in which ossification of both iliaci followed forcible manipulation of a flexed and adducted hip-joint. The common history of all such cases is the reception of an injury, such as a kick or blow, rupture of the muscle from over-action, or in the case of the brachialis anticus laceration of the muscle accompanying a dislocation of the bones of the forearm backwards. The injury may be followed immediately by the development of a hæmatoma, the swelling consequent on which may persist until the more lasting hardening due to the ossification appears. More commonly a latent interval or a period of improvement is followed in from 10 to 21 days by the development of local pain and limitation in the movements of the neighbouring articulation. A hard resistant tumour is then discovered in the area of the affected muscle, which may persist permanently, for long periods, or become more or less completely absorbed with some rapidity. The cases are as follows:—

CASE 1.—A youth aged 19 years. Six weeks before admission, in July, 1905, the patient received a kick on the front of the left thigh while playing football. He had received the same injury on two previous occasions, but treatment with hot fomentations caused the swelling to disappear in two or three days. On this occasion there were bad bruising and considerable swelling of the knee which after a few days completely disappeared. Two weeks later the patient noted that the thigh had commenced to swell again and a "lump" formed which gave him considerable pain, especially on flexion of the knee. The swelling had not increased during the past two weeks, and the patient had been able to use his limb more freely. As a shop assistant he is on his feet most of the day. On admission an obvious swelling existed in the middle third of the front of the thigh; the superjacent skin was normal in appearance and temperature. The swelling was fusiform in outline; at its upper and lower ends the femur could be palpated at a deeper level. The inner margin of the swelling was somewhat sharply defined. There was no pain or tenderness on palpation, but flexion beyond half the normal range caused pain, while no movement was produced of the tumour. A skiagram showed a definite plate of bone somewhat to the outer side of the femur and unconnected with the bone. The patient was kept at rest for seven weeks, during which time the tumour somewhat diminished in size and became less defined in outline. He then returned to his work, and has since suffered no practical disability. A skiagram taken on Feb. 3rd, 1911, five years later, showed no trace of the previous ossification. The movements of the knee were normal, and no swelling could be detected on palpation. The patient continues to box and play football.

CASE 2.—A youth aged 19 years. Three months before admission, in July, 1905, the patient received a kick from a horse on the front of the right thigh. The kick was a severe one, necessitating rest in bed for a week. Swelling was noted on the day following the accident, and the patient did not consider that this had either materially increased or diminished since. There had been little pain, except on going upstairs; at times the limb felt as if "giving way under him." On admission to the hospital a swelling of fusiform outline and 5 in. in length was found over the front of the middle third of the femur. It was quite hard and immovable, apparently fixed to the anterior surface of the bone. The skin was somewhat stretched over it, the superficial veins were dilated, and a small pigmented area corresponding to the point actually kicked still existed. A skiagram showed the tumour to be composed of bone of about the same consistence as normal cancellous tissue. For about an inch at the central part no interval could be demonstrated between the tumour and the femur, but the two ends of the tumour were quite free from the bone. The arrangement of the laminæ suggested that the tumour consisted of an ossification in the substance of the quadriceps. On July 19th, 1905, Mr. H. H. Clutton exposed the tumour by a longitudinal incision on the front of the thigh and removed the greater part of it. The bony mass was surrounded by gelatinous layers suggesting bursal tissue. Some septa of similar tissue and what appeared to be muscle ran for some distance into the new bone. The periosteum was not exposed. Except for the development of a hæmatoma the wound healed normally and the patient left the hospital on the nineteenth day after the operation. A skiagram taken on Feb. 1st, 1911, shows a plate of bone about half an inch in thickness closely applied to the femur beneath the site of the upper part of the original ossific tumour. The patient has been doing his work as a railway porter for the past five years, suffering no disability except slight restriction in the amount of flexion possible at the knee. No tumour is detectable on palpation.

CASE 3.—A man aged 23 years. Seven weeks before he came under observation, while playing football the patient had an accident, another player falling over him and kicking his knee. A week later, while playing football again, an onlooker pointed out to him that he had "water on the knee." For the next six weeks he was kept at rest and treatment directed to the injury to his knee. At the end of seven weeks he came under my notice, when a hard fusiform tumour was present over the middle third of the femur. Flexion of the knee could only be carried out to about half the normal range, and attempts at further movement were painful. A skiagram showed a large mass of bone in the deep part of the quadriceps, no interval existing between it and the femur. It was well formed delicate bone in irregular lamellæ. The femur was normal. The patient was kept at entire rest and given small doses of potassium iodide for four weeks, at the end of which time the bony swelling had become less in extent, but somewhat denser. During the next three months the patient gradually resumed normal life and exercise, and at the end of the period was suffering no disability although some swelling was still palpable.

The chief interest in these cases lies in the first and second, since the patients were of the same age, they came under observation at the same time, and while one was treated by an active method, the other practically got well spontaneously. It is, however, to be remarked that the first case was of seven weeks' standing only, while the tumour in the second patient had been in existence three months. None the less, I am inclined to maintain the opinion that no active treatment should be adopted in the early stages of the condition, and I think that this view is supported by the observation here recorded in spite of the difference in the duration of the condition in the two patients.

I regret that I am unable to attempt to shed any new light on the pathology of traumatic myositis ossificans. I think we can only assume that patients the subjects of the condition belong to the "ossific diathesis" of Virchow—that is to say, in the words of Mr. Shattock in describing a traumatic osteoma, that "they possess an idiosyncrasy for producing bone under conditions which do not avail under normal circumstances." These patients must, in fact, be placed in the same category with those in whom large masses of callus are developed in connexion with fractures, even to the degree of such a case as the remarkable instance recorded by Battle and Shattock in which the callus assumed the form of an actual cancellous osteoma.

The frequency with which two muscles of the body, the quadriceps extensor femoris and the brachialis anticus, are affected seems to me to support the theory that the exciting

[1] A paper read before the Surgical Section of the Royal Society of Medicine on March 14th, 1911.

influence is to be referred to bone-forming cells detached from the periosteum. Both these muscles obtain a great part of their origin from plane surfaces of bone to which the attachment of the periosteum is not so firm as at the bony ridges or eminences which afford so great a proportion of muscular attachments, hence it seems probable that the tearing free of fibres of origin of these muscles may more readily give rise to breaches of the continuity of the periosteum, which, while in themselves insignificant, may yet suffice to set free bone-forming cells from the osteogenetic layer of the periosteum in a number capable of providing the necessary genetic stimulus for the ossific process. Such breaches of continuity of the periosteum may be very far short of a gross lesion such as accompanies a fracture and yet be sufficient for the purpose, while the subsequent apparent complete absence of continuity between the tumour and the bone is explained by the retraction of the separated fibres of muscle together with their minute attached portions of periosteum into the main mass of the muscle.

As to the common subsequent re-absorption of the bone, this appears to me to be a process in strict conformity with the re-absorption of superfluous masses of provisional callus in the case of fractures, the remodelling of bones to compensate for deformity due to curvatures, or the re-absorption of such cancellous osteomata as is described in the case of Battle and Shattock already referred to.

The structure of the bone is that of typical cancellous tissue except for the absence of true bone marrow, not differing in any way from that developed on the surface of the long bones in cases of osteo-periostitis. To illustrate this fact I exhibit a skiagram of a femur affected with diffuse osteo-periostitis of unknown origin, in which the ossification extends into the origin of the vastus externus, while the compact tissue beneath the periosteum has been extensively absorbed. A microscopical section of the bony tissue in this instance is identical in structure with the section obtained from the case of traumatic myositis ossificans, except in so far as the trabeculæ and intertrabecular spaces are more delicate in arrangement.

Significance has been attributed to the development of a hæmatoma in the early stage of the condition, but the presence of blood is probably only of importance in so far as it dissects up the intimate structure of the affected muscle and opens up the way and forms the basis for the connective tissue in which the subsequent ossification takes place. It has been suggested by Ewald in a recent paper that the escape of synovial fluid from the knee and elbow-joints respectively affords the stimulus for the ossific process. In support of this theory Ewald dwells upon the bursal character of the tissue surrounding the bony mass (mentioned in Case 2), which has been described by many observers, and also on the synovia-like fluid filling the cystic cavities which sometimes develop. It may be pointed out that similar tissue and fluid are observed in some cases of false joint following non-union of fractures where no rupture of a neighbouring synovial capsule exists.

We should be careful clinically to separate the condition of traumatic myositis ossificans from the ossifications accompanying the separation of small bony prominences, as in dislocations of the elbow, since these are much less extensive, usually confined to fibrous tissue, and in my experience more likely to be permanent. Again, traumatic myositis ossificans should be sharply distinguished from the so-called "rider's bones" which are really small permanent exostoses, and rather to be classed with the normal muscular apophyses which develop on bones at the points of attachment of powerful muscles as a definite response to the mechanical stimulus furnished by the pull of the muscles. In support of this view it may be pointed out that when the "rider's bone" attains large proportions, as in the ossification of the complete adductor magnus, the change is a permanent one. It does not appear to me to be correct to class the ossifications of muscle observed in various neuropathic diseases with traumatic myositis ossificans, since the former are permanent degenerations due to disturbances of nutrition, while the latter are rather to be regarded as connected with the normal process of repair.

Lastly, as to the general line of treatment to be adopted, a period of some weeks' complete rest should be maintained during the continuance of the active progress of ossification. When it is judged by clinical observation and X ray examination that progress has ceased or the process is retrogressive massage and exercise should follow. Operative treatment should only be considered when the process has manifestly come to a definite standstill, and the patient suffers from functional disability which there is a chance of relieving.

Upper Brook-street, W.

# THE FORMATION OF BONE IN PERIOSTEUM SEPARATED BY INJURY.[1]

BY A. A. BOWLBY, C.M.G., F.R.C.S. ENG.,
SURGEON TO ST. BARTHOLOMEW'S HOSPITAL.

THE condition to which I wish to direct attention is well illustrated by the two following cases.

CASE 1.—A young man, aged 18 years, was thrown from his horse on April 20th of last year and injured his arm, the pain being felt on the flexor aspect just above the elbow-joint. As it was evident that he could not have struck this region, it appeared probable that the injury was caused by a muscular wrench when he fell on his outstretched hands. He was seen the next day by Dr. Brice Collyer of Croydon, who found that there was a good deal of swelling and pain, but the X rays confirmed the fact that there was no fracture. During the next fortnight the swelling rather increased and the patient was not able to use the arm, while both flexion and extension became more limited. On May 26th another radiogram showed that there was an irregular piece of bone in the region of the swelling, and on May 30th I saw the patient and found the following condition. Situated on the front of the humerus under the biceps tendon was an irregularly rounded swelling of the size of a hen's egg. It was very firm and was more or less fixed to the bone, but the muscle over it was free. It limited the movements of flexion and extension, and when the forearm was as nearly completely extended as possible it could be seen as a very definite swelling. An X ray picture showed an irregular formation of bone over an area of about 1¼ in. in diameter. The arm was placed on a splint and Scott's ointment was applied, with the result that in six weeks the swelling had almost disappeared. In three months' time no sign of it could be found and the movements of the arm were quite restored.

CASE 2.—A young lady, aged 21 years, fell while tobogganing on April 15th and injured her elbow. A surgeon found that she had sustained a dislocation of this joint and this was reduced under an anæsthetic, and the arm kept in a splint for one week and in a sling for a week more. It was then found that there was a swelling on the front of the humerus just above the elbow-joint, and this swelling continued to increase till I saw her six weeks after the accident. I found a swelling exactly like that described in Case 1 and, like it, of about the size of a hen's egg, situated beneath the muscles and attached to the bone. It caused aching pain and prevented free use of the arm. The X rays showed an irregular bony lump separated from the outline of the humerus by about an inch, while the shaft of the bone itself was normal and uninjured. Here, also, rest on a splint and a mercurial ointment resulted in the complete disappearance of the swelling within three months and the restoration of movements in this joint.

The formation of a considerable swelling as a result of the separation of periosteum by the muscles is not a common occurrence, although, as the result of direct blows, such as kicks on the shin, it is frequently seen. But I believe that there are really a great many cases in which pain and impairment of the use of a limb are caused by the dragging of the periosteum off the bone where large muscles are inserted into it, and by the hæmorrhage which results therefrom and from the formation of new bone. In most of these cases the swelling is slight and is often hardly noticed, but pain may persist for a long time unless the muscles are kept at rest. If there has been any old periosteitis which has left the membrane hypervascular and has loosened its

[1] A paper read before the Surgical Section of the Royal Society of Medicine on March 14th, 1911.

attachment, separation is more easily caused, and I have seen in one patient, who had previously had acute osteitis and necrosis of a small piece of the humerus, several attacks of pain and swelling of the bone brought on by any violent use of the muscles attached to the upper part of the affected bone. The patient was liable to these attacks for several years, and they caused the arm to swell to at least double its natural size, but they only occurred as a result of some considerable muscular strain, and slowly subsided when the arm was kept absolutely at rest.

In their less pronounced form I have seen cases of pain and tenderness with some swelling, which I have attributed to a separated periosteum, chiefly in the humerus and the femur, but the only cases where X ray pictures have been taken to confirm this diagnosis are the two I have detailed above. In one of them the swelling was so considerable that it had been diagnosed as a possible periosteal sarcoma.

Manchester-square, W.

## A CASE OF POISONING BY TRAGOPOGON PRATENSE, OR GOAT'S BEARD.

BY FRED J. SMITH, M.D. LOND.

*With Notes on the Chemistry by* HUGH CANDY, B.SC., F.I.C.

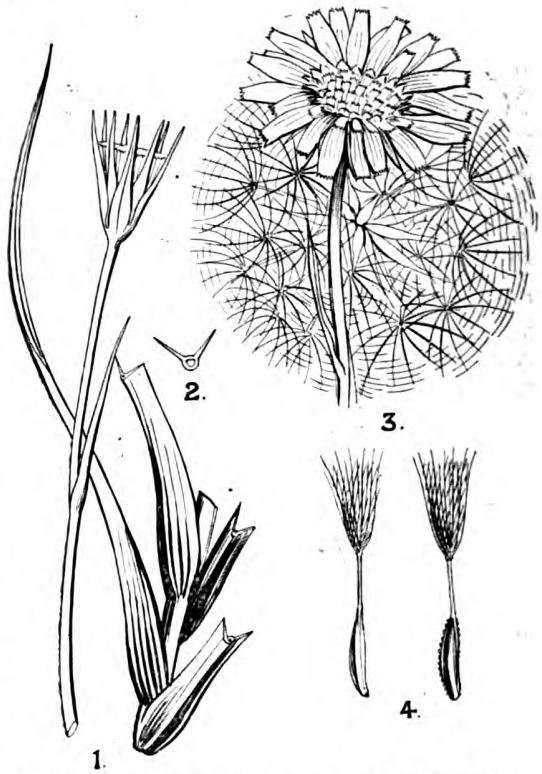
ON Monday, July 18th, 1910, the patient, a boy, aged 13 years, was admitted to the London Hospital in a semi-comatose state with the following history. On the previous Saturday afternoon, in company with some school fellows, he had been for a walk near Epping Forest and had partaken somewhat freely of what seem to be known locally as "gipsy nuts." He took a supply home with him and ate some more on Sunday. No ill-effects appear to have been caused either on the Saturday or during Sunday, for he went to bed on Sunday night apparently well, but was found on Monday morning semi-conscious in bed, looking very blue, and complaining of headache, but apparently there was no vomiting or other symptom of active irritant poisoning. (I believe that emetics were administered at home, and that they acted very successfully.) As he did not get better he was admitted to the hospital in the course of Monday afternoon, when I saw him at the request of Dr. R. Cecil Wall, under whose care he was admitted, and to whom I am indebted for permission to publish the case. When we saw the boy he was unconscious, cyanosed, with small inactive pupils, a small quick pulse, breathing very rapidly, with crepitations over both lungs. The temperature on admission was 101° F. Hot coffee and simple stimulants were administered, but in consideration of the long time that had elapsed since he had taken the deleterious material, the nature of which was quite unknown, and also fearing we might do more harm than good by very energetic treatment, we contented ourselves with one injection of strychnine (1/60 gr.) and atropine (1/100 gr.), the former as a general stimulant, and the latter in the hope that it might be anti-dotal, as the pupils were contracted. He passed several loose motions under him in bed, his respirations became of a Cheyne-Stokes type, his temperature gradually rose to 104°, and without showing any marked symptoms beyond those mentioned he died on Monday evening.

It was tolerably obvious that death was due to the "gipsy nuts." How many the boy had eaten is uncertain, but probably a good many, as he collected a pocketful after his feast when out for the walk, and of these he would seem to have eaten freely on Sunday. His mother brought some for us to examine. I only recognised them as the seeds of some composite plant and asked to be supplied with some other parts of it; these in a day or two were forthcoming when one, of course, at once saw that it was the common wild flower Tragopogon pratense, which can be found fairly abundantly about waste ground, rubbish heaps, &c.

The post-mortem examination was done on the next day. Its results were entirely negative, with the exception of a small patch of about the size of a penny of acute gastritis close to the œsophageal opening, and a few tiny hæmorrhages in the lungs, no doubt caused by respiratory distress and failure. As vomiting and purging had been rather severe I did not preserve any of the contents of the guts for analysis, though they were very carefully examined with the naked eye with negative results.

On turning to my Sowerby I find no mention of any poisonous property residing in the plant—in fact, it is there stated that the roots of this and its brother Tragopogon porrifolius are good to eat. As the plant is, however, so common I think the case ought to be published as a warning of the possible dangers of eating it.

As soon as I knew what plant it was that had caused the fatality I obtained some of the seeds for analysis by Mr. Hugh Candy, analyst to the hospital, whose report is appended.



1. The plant (much reduced). 2. Section of a leaf. 3. Flower and pappus (about hal f natural size). 4. The seeds "gipsy nuts" (about half natural size).

*Notes on Examination of Seeds of Tragopogon Pratense for Presence of Alkaloids, by* Mr. CANDY.

Of the seeds 100 grammes were ground in a mill, and the crushed product was repeatedly extracted with alcohol in presence of tartaric acid; the alcoholic extract was filtered, and the clear filtrate had a fine green colour; this filtrate was evaporated on the water bath to a soft residue which was of a deep brown colour. This residue was dissolved in hot distilled water as far as possible and the solution was filtered. The aqueous filtrate was made up to 200 c.c. with distilled water and then divided into two equal portions, $S_1$ and $S_2$, which were examined differently as follows:—

$S_1$. 100 c.c. were purified by the usual process with lead acetate, and the final lead-free filtrate was tested for alkaloids with the usual reagents. A precipitate was only obtained with phospho-molybdic acid.

$S_2$. The other 100 c.c. were successively extracted with (1) petroleum ether, (2) benzene, and (3) chloroform, first in acid solution and afterwards in ammoniacal solution. The last alkaline liquid was finally extracted with (4) amyl alcohol. In this way seven extracts were obtained, which were separately evaporated, and the residues so obtained were individually tested for alkaloids *with negative results.* The residue of $S_2$ from which these extracts had been obtained still gave the precipitate with phospho-molybdic acid.

Therefore, this precipitate is due to some other principle which is not an alkaloid proper, for it is not extracted by the ordinary alkaloid solvents and is not precipitated by I in KI, or Mayer's solution.

A portion of $S_1$ was also rendered alkaline with ammonia

and extracted with chloroform; this extract after evaporation was tested for alkaloids with negative results. The residue of $S_1$, however, still gave the precipitate with phosphomolybdic acid.

Harley-street, W.

# A RECORD OF 90 DIPHTHERIA CARRIERS.

BY ANGUS G. MACDONALD, M.B., C.M. EDIN., D.P.H. VICT.,

LATE BACTERIOLOGIST TO BOROUGH OF CREWE AND ASSISTANT TO MEDICAL OFFICER OF HEALTH OF CREWE.

As in typhoid fever, so in diphtheria, the carrier must be regarded as an important factor in the spread of disease.

The following tables are the result of an analysis of the findings of a bacteriological investigation of diphtheria in the borough of Crewe during a period of six months—March to September, 1910. The corporation of Crewe have been generous in supporting the carrying out of the investigation; and Dr. G. Granville Buckley, medical officer of health of the borough, has given his kind permission to use the records.

I shall be gratified if my criticism of the results should be accepted by my colleagues as a contribution towards the study of diphtheria, especially as regards the prevention of its spread. The term "carrier" or "positive contact" here used applies to persons who on examination were found to harbour the bacillus of diphtheria. The situations usually examined for the bacillus were the throat and nose, and the only other situation where the bacillus was found in this investigation is the ear. By examination of the throat is meant careful swabbing of the tonsils and pharynx; and of the nose, the passage of a swab slowly and carefully in and out through one or other nostril, separate swabs being used for each nostril.

Examination was undertaken on account of contact with a notified case of diphtheria, and the "contacts" were roughly divided into "home contacts" and "school contacts." Home contacts include the members of the family of the notified person, and also of neighbours and friends with whom contact about home was suspected or suggested. School contacts include all those examined at school, or rarely at workplace, on account of their contact with a notified person. The scheme of swabbing had to be modified at various times to suit circumstances and with a view to getting the best results, and in the end the attempt was always made to make the swabbing as wholesale as possible. The people have aided the efforts of the health authorities with wonderful readiness, but in various quarters opposition naturally was met with, which tended to lessen the satisfactory nature of the results and probably retarded the stamping out of the disease.

In a further paper I hope to discuss the epidemic in all its bearings, but meanwhile shall limit criticism to the carrier problem.

For the sake of comparison and of giving an idea of the relative proportion of things I give in tabular form the number of notifications received during the six months under consideration, and also various figures representing the amount of "contact" work done. The tables speak for themselves, and I have drawn out no percentage estimates or averages for any of the figures, having poor opinion of the utility of doing so, as the amount of work done—the estimation of the number and nature of the contacts to be examined, and the persistency with which the examination is followed out—is so much a personal and also local matter that no comparison could well be instituted with the work of others.

In the table of contacts, again, the approximate duration of known infectivity is given, and no average is struck. It is evident that the known period of infectiveness gives little idea of the whole period of infectiveness, and that even the known period would vary in different hands according to the local conditions—the facility afforded by the people for re-examination and the strength of the public health staff. It is evident, also, that to strike an average of known duration of infectiveness between cases that are found infective for some few days, and others whose infectiveness continues over a period of months, would be of no practical utility.

TABLE I.—*Showing the Number of Cases Bacteriologically Examined during the Months March–August, 1910.*

| 1910. | Notified and suspected cases. | Contact cases. | | | For release from quarantine: Hospital and home cases and contacts. | Total cases examined. |
|---|---|---|---|---|---|---|
| | | Home. | School. | Total. | | |
| March ... | 43 | 65 | 49 | 114 | 56 | 213 |
| April ... | 70 | 117 | 99 | 216 | 140 | 426 |
| May ... | 95 | 95 | 101 | 196 | 141 | 432 |
| June ... | 63 | 106 | 171 | 277 | 148 | 488 |
| July ... | 61 | 83 | 31 | 114 | 159 | 334 |
| August ... | 42 | 68 | 193 | 261 | 130 | 433 |
| Totals ... | 374 | 534 | 644 | 1178 | 774 | 2326 |

The above table shows the relative proportion of cases actually examined, and does not include subcultures or duplicates, except of examination for release from quarantine.

It will be seen that the number of notified and suspected cases in March is fewer than the number of notified cases as shown in Table II., while in the other months that number is considerably higher than the notified number. The reason is that at first all the notified cases were not bacteriologically examined as they were afterwards, nor until the work was in full swing was there the same assistance from the medical practitioners, teachers, and others in bringing to notice suspected cases. In the schools the teachers took up the work of observation with enthusiasm, and all the children brought under observation were swabbed and referred at once to their medical attendant for treatment, whatever the condition might be.

TABLE II.—*Showing the Number of Cases of Diphtheria Notified in each of the Six Months, March–August; the Number of Contacts Examined, and those found Positive.*

| 1910. | Number of notifications. | Number of contacts examined. | | | Number of contacts found positive. | | |
|---|---|---|---|---|---|---|---|
| | | Home. | School. | Total. | Home. | School. | Total. |
| March ... | 49 | 65 | 49 | 114 | 13 | 7 | 20 |
| April ... | 31 | 117 | 99 | 216 | 15 | 3 | 18 |
| May ... | 25 | 95 | 101 | 196 | 10 | 3 | 13 |
| June ... | 27 | 106 | 171 | 277 | 11 | 10 | 21 |
| July ... | 15 | 83 | 31 | 114 | 10 | 5 | 15 |
| August ... | 10 | 68 | 193 | 261 | 3 | 0 | 3 |
| Totals ... | 157 | 534 | 644 | 1178 | 62 | 28 | 90 |

It may be observed in connexion with this table that the cases of diphtheria found as the result of bacteriological examination of notified cases are fewer than the notified cases by a small and varying percentage, being smaller when there is much diphtheria and greater when there is little.

The chief point brought out in Table II. is the proportion of contacts found positive to contacts examined, and the relative proportion of positive home contacts to school contacts. The number of school carriers is also unduly inflated by the inclusion of 12 cases who were included on suspicion, and whose after-examination led to the belief that the bacilli which were the cause of suspicion were after all not B. diphtheriæ. They had characters sufficient to justify temporary observation in the presence of an outbreak of diphtheria, and the temporary quarantine and suspension from school were little hardship and a measure of safety.

All school carriers were found to be intimately associated at play with other cases and carriers, and mere class-room proximity was found to be of little importance as a factor in spreading the disease. The evidence all goes to indicate the very intimate means necessary for the transmission of diphtheria from one individual to another. In the home the positive cases have been found in most number amongst those who are naturally in closest communication, and the same holds for playmates in the same street and at school. This fact is of great importance, and indicates how readily, by prompt bacteriological examination and detection of positive cases, the dissemination of the disease may be prevented.

TABLE III.—*Details of 90 Carriers.*

| No. | Sex and age. | Known duration of carrier period. | Remarks. |
|---|---|---|---|
| 1 | M., 12 | 6 weeks. | School suspect; bacilli in throat four weeks; in nose six weeks. Cases of diphtheria in his class. |
| 2 | M., 16 | 5 days. | Home contact of notified case. No history of illness. |
| 3 | F., 6 | 3 weeks. | School contact of notified case. No history of illness. |
| 4 | M., 3 | 5 ,, | Brother and sister home contacts; family of seven. Case at school where were other cases. |
| 5 | F., 1 | 3 ,, | No discoverable previous or current illness of carriers. |
| 6 | F., 6 | 3 ,, | School contact. No evidence of illness. |
| 7 | M., 6 | Not ascertained. | School contact; notified two days later; treated at home; no other swabs obtainable. |
| 8 | M., 6 | ,, | School contact; left the district before another swab was obtained. |
| 9 | M., 9 | 2 weeks. | Home contact, brother of No. 20. No illness. |
| 10 | M., 7 | 1 week. | School contacts of No. 20. No illness admitted. |
| 11 | F., 7 | 2 weeks. | |
| 12 | M., 7 | 2 ,, | Home contact. No illness. |
| 13 | M., 7 | 2 ,, | ,, ,, |
| 14 | F., 8 | 2 ,, | ,, ,, |
| 15 | F., 7 | 2 ,, | School contact. No illness. |
| 16 | M., 11 | 4 ,, | Home contact, brother of No. 17; got no antitoxin; notified two days later. |
| 17 | F., 7 | 4 ,, | Home contact, sister of No. 16; got antitoxin; no evidence of illness. |
| 18 | F., 7 | 4 ,, | School contact. No illness. |
| 19 | M., 25 | Not ascertained. | Home contact; out of work. Nursed notified sister on his knee. Went off to work 10 days later without having been re-examined. |
| 20 | M., 7 | 15 weeks. | Brother of No. 9. Bacilli remained in nose and throat; allowed to leave hospital under his medical man's supervision. Successive negative swabs obtained 10 days later. |
| 21 | M., 10 | 8 days. | Home contact. No illness. |
| 22 | F., 15 | 2 weeks. | Home contact of No. 23; not examined when No. 23 went to hospital. No sign of illness. |
| 23 | M., 6 | 2 ,, | Discharged from hospital; found positive in nose a week after discharge. |
| 24 | M., 27 | 3 days. | Father, mother, and brother of notified case. No illness; got antitoxin. |
| 25 | F., 26 | 3 ,, | |
| 26 | M., 1 | 3 ,, | |
| 27 | M., 13 | Not ascertained. | Home contacts; four cases notified simultaneously; these then found negative. Baby of eight months notified a month later, when these were found positive; further examination obstructed. |
| 28 | F., 6 | ,, | |
| 29 | F., 35 | 2 weeks. | Home contact, mother of notified case. No illness. |
| 30 | F., 13 | 3 ,, | School contact. No illness. |
| 31 | F., 12 | 3 ,, | ,, ,, ,, |
| 32 | F., 10 | 4 ,, | Home contact. No illness. |
| 33 | F., 6 | 3 ,, | School contact. No illness. |
| 34 | M., 27 | 12 days. | No. 34, home contact of No. 35. No. 35 was discharged from the hospital after three months' residence; remained positive in pus from ear; one negative result before discharge. Found positive and virulent eight months from onset of illness. |
| 35 | F., 45 | 8 months and still positive. | |
| 36 | F., 43 | 3 months. | Home contact. No illness. |
| 37 | F., 10 | 2 weeks. | Home contact. Vague history of "cold" and "sore throat" some weeks before. |
| 38 | M., 7 | Not ascertained. | Home contact. No admitted illness; slight membranous rhinitis; bacilli found in nose; not re-examined. |
| 39 | F., 10 | 6 weeks. | Home contacts. No illness; had antitoxin. Sisters. |
| 40 | F., 16 | 6 ,, | |
| 41 | F., 31 | 5 ,, | Home contact of baby 1 year old. Atrophic condition of nasal and pharyngeal mucosa; a laundry worker; probably introduced the disease to home. |
| 42 | M., 1 | 3 ,, | Home contact, brother of Nos. 39 and 40; had no antitoxin; notified two days later. |
| 43 | F., 5 | Not ascertained. | School contact. No illness; not re-examined. |
| 44 | M., 5 | ,, | ,, ,, |
| 45 | M., 5 | ,, | School contact. Bacilli found in nose with membranous rhinitis; lost sight of. |

TABLE III. *(continued).*

| No. | Sex and age. | Known duration of carrier period. | Remarks. |
|---|---|---|---|
| 46 | M., 10 | 4 weeks. | Notified as scarlet fever; found also to carry B. diphtheriæ in throat. |
| 47 | F., 11 | 3 weeks. | Home contacts. No illness; antitoxin given; sisters; two others in hospital. |
| 48 | F., 14 | 3 ,, | |
| 49 | M., 3 | 3 ,, | Home contact. No illness; got antitoxin; one of family discharged from hospital two weeks before; found negative; other infection probable. |
| 50 | M., 9 | 4 ,, | Home contact. No illness. |
| 51 | M., 14 | 4 ,, | Home contact. No illness. At date of last examination found delivering bread from handcart. |
| 52 | F., 41 | 6 ,, | Home contact; mother of Nos. 39, 40, and 42. |
| 53 | F., 6 | Not ascertained. | Discharged from hospital ten days before brother notified. Found positive in nose; mother (No. 36) still positive. |
| 54 | M., 10 | ,, | Home contact. No illness; no antitoxin; no pretence of isolation; three others in family notified during next fortnight. |
| 55 | M., 5 | 13 weeks. | Home contact; examination not obtained until after fresh case in own and next door family. |
| 56 | M., 5 | 12 ,, | Home contact; two days before found getting sweets straight from mouth of No. 55. |
| 57 | F., 19 | 2 days. | Home contact. No illness. |
| 58 | M., 7 | Not ascertained. | School contact; lost sight of. |
| 59 | M., 7 | 3 weeks. | School contact ,, ,, No illness in self or family. |
| 60 | M., 7 | 2 days. | |
| 61 | M., 7 | 3 weeks. | |
| 62 | M., 7 | 4 ,, | School contact; found No. 67 positive, had sore throat ten days before; also No. 66 notified later. |
| 63 | M., 7 | 3 ,, | School contact; no complaint. Found No. 68 at home positive. |
| 64 | M., 7 | Not ascertained. | School contact; no complaint; lost sight of. |
| 65 | F., 8 | ,, | Home contact; no illness; re-swabbing not obtainable. |
| 66 | F., 6 | 3 weeks. | Sister of No. 62; found at home positive; notified two days later, before antitoxin given. |
| 67 | M., 9 | 3 ,, | Brother of No. 62; glands enlarged; had "mumps" ten days before. |
| 68 | M., 2 | 3 ,, | Brother of No. 63; had antitoxin at once; no symptoms of illness. |
| 69 | F., 7 | 2 ,, | Scarlet fever case in hospital; possible school contact; bacilli proved virulent. |
| 70 | F., 5 | 1 week. | School contacts. For various reasons on suspicion included as carriers, but as repeated examination of cultures failed to yield isolated colonies of B. diphtheriæ the cases were not followed. |
| 71 | F., 5 | Not ascertained. | |
| 72 | M., 5 | ,, | |
| 73 | M., 6 | 2 weeks. | School contact; frequent sore throats; no notice taken of recent illness. |
| 74 | M., 6 | Not ascertained. | School contacts. No. 73 alone of this group gave a pure culture, and as holidays supervened the cases could not easily be found for further swabbing. |
| 75 | F., 6 | ,, | |
| 76 | M., 6 | ,, | |
| 77 | F., 6 | Not ascertained. | School contact. |
| 78 | M., 7 | 3 weeks. | Scarlet fever case; probable school contact. |
| 79 | F., 7 | Not ascertained. | Home contact; had "rheumatic fever" shortly before; further swabbing refused. |
| 80 | F., 21 | 4 weeks. | Home contact ,, ,, No symptoms of illness; got antitoxin. |
| 81 | F., 2 | 4 ,, | |
| 82 | M., 11 | 4 ,, | Home contact; no illness; got antitoxin. |
| 83 | M., 7 | 7 ,, | Home contact; chronic membranous rhinitis; bacilli proved virulent. |
| 84 | F., 4 | 4 ,, | Home contact. ,, ,, No illness; had antitoxin. |
| 85 | M., 16 | 2 ,, | |
| 86 | M., 3 | 3 ,, | |
| 87 | F., 9 | 3 ,, | Home contact; notified a day later, before having antitoxin. |
| 88 | F., 41 | 1 week. | Home contact; no illness. |
| 89 | M., 13 | 1 ,, | Home contact; son of No. 88. |
| 90 | F., 8 | 6 weeks. | Scarlet fever case; acute and lingering rhinitis; bacilli proved virulent. |

Antitoxin was recommended in all cases of immediate contacts, positive or negative, and administered in most, although it has not been possible to ascertain the number of cases who had antitoxin privately administered.

In criticising the series of carriers set out in Table III., it will be seen that they may be divided into four definite groups. First, there are those who show no clinical evidence of diphtheria and in whom the bacillus diphtheriæ is found for a short time. These persons probably possess some immunity or have a bacterial flora in the mouth or nose inimical to the bacillus diphtheriæ. Secondly, we find cases in whom a history of "cold," "sore-throat," "mumps," &c., some time previously may be elicited. They may also have some form of paralysis, and are obviously neglected cases of diphtheria. Thirdly, there are cases without a clinical history of diphtheria, but with some local lesion of the throat, nose, skin, ear, &c., where the bacillus diphtheriæ finds continued lodgment—membranous rhinitis is the most common lesion found. Fourthly, akin to the third group are those who have passed through a definite attack of diphtheria, and in whom usually associated with some pathological lesion the bacillus diphtheriæ remains for lengthy periods after convalescence.

The diagnosis of these carriers was, in the largest proportion, made from microscopical demonstration of the bacillus diphtheriæ obtained from isolated colonies. The exceptions mentioned in considering Table II. were temporarily diagnosed from bacilli observed in mixed preparations—the microscopic preparations are extant. "Virulence" is probably legitimately assumed where morphologically typical diphtheria bacilli are found in individuals intimately associated with clinically and bacteriologically typical cases of diphtheria. In a few cases where doubts as to virulence might be raised—the scarlet fever cases and the prolonged cases—virulence was established by the physiological test at the Public Health Laboratory, Manchester, under the supervision of Professor Sheridan Delépine, to whose courtesy and kindness the permission to use the reports is due.

As a rule, when a carrier is found in association with a case there is nothing, except history of previous contact, to indicate which carried the bacilli to the other, although in some cases a pathological lesion or the bacterial flora may suggest a long-time carrier.

The fate of the bacillus diphtheriæ when it disappears from an infected person is not obvious. There is no evidence of phagocytosis in the affected regions; and the most probable explanation is that it disappears before the growth of some organism for which the environment for the time being is more favourable. The total disappearance of the bacillus diphtheriæ is very surprising in those cases where it is found for only a short time. In the chronic cases it seems usually to beat a slow retreat before a staphylococcus; and "ghost" forms of bacillus diphtheriæ are commonly to be found amongst the staphylococci for some time after the bacilli have ceased to be successfully isolated.

In some of the chronic carriers attempts have been made to implant on the pharynx and nasal passages flora which observation suggested might be inimical to the growth of the bacillus diphtheriæ; but although some of these implanted organisms were recovered on subsequent swabs, the bacillus diphtheriæ continued to grow. It seems probable, nevertheless, that further prosecution of work on these lines may result in finding harmless organisms whose implantation and growth on diphtheria-infected persons may result in ousting the bacillus diphtheriæ from its usual haunts. The administration of antitoxin has no apparent effect on the persistence of the bacillus diphtheriæ in carriers any more than in cases.

In addition to the foregoing observations the lesson of these carriers may be briefly summed up as follows:—

1. Carriers are found at all ages and of either sex.
2. The previous carrier period cannot be ascertained, but may in some cases be inferred.
3. Nor can it be said in many cases that one case was derived from another—that is, the carrier found may have given the disease to those around, or may only have just received it.
4. The presence or absence of an obvious pathological condition is no criterion of the fact of a carrier, of the length of carrier life, or of virulence.
5. The length of carrier life seems to have no effect on virulence: bacilli have been demonstrated to be virulent after four and eight months in the ear and nose of different individuals.
6. Carriers are found amongst those most intimately associated with other carriers or cases; at home between mother (nurse) and child, and child and child who play together; at school the carriers found are few and always closely associated (in play and not necessarily in school-room proximity) with some other carrier or case.
7. The control of diphtheria depends (assuming control of the case) on the control of the carrier.
8. The carrier should be notified as a case of diphtheria, no matter of what age or sex, and due quarantine and observation should be maintained until satisfactory demonstration of the disappearance of the bacillus diphtheriæ.
9. As everything points to the conclusion that the bacillus diphtheriæ is essentially a human parasite (a saprophytic existence is not evident; the transference from animal to human is at any rate rare, and many cases of apparent transport by milk and other agencies are manifestly from human contact), a determined attack on the lines of thorough bacteriological investigation should have no difficulty in stamping out diphtheria altogether from the land.
10. Evidence points also to the slow, inevitable, mechanical distribution of the disease which persists endemic in the undiscovered carriers. Epidemicity depends entirely upon the number and nature of the carriers; the headway that has been attained before preventive measures have been effectively used, and upon various sociological factors more or less under the control of the authorities. The invocation of miracle, of meteorological factors local and universal, of special intensity of the virus, *et omne ignotum*, which is the commonplace of authority to-day, might surely give way to the recognition of simple, natural, open-eye causation.

# GRAVE AND PROLONGED CARDIAC FAILURE FOLLOWING THE USE OF COCAINE IN DENTAL SURGERY.

BY FREDERICK W. PRICE, M.D. EDIN., M.R.C.P. LOND.,
PHYSICIAN TO THE GREAT NORTHERN CENTRAL HOSPITAL; PHYSICIAN AND HONORARY PATHOLOGIST TO THE MOUNT VERNON HOSPITAL FOR DISEASES OF THE CHEST;
AND
A. B. LEAKEY, M.B., C.M. EDIN.

AT a time when the question of the administration of local anæsthetics by unqualified persons is attracting attention we think it desirable that the following case should be put on record. In our opinion it illustrates in a striking manner the risk with which such is accompanied. Not only did the patient have a remarkable escape from death at the time, but she had a dangerous relapse several weeks after, and was seriously ill for some months.

The patient was a woman, 34 years of age. Her previous illnesses were occasional "sore-throat" during childhood, scarlet fever at 19 years of age, and two attacks of influenza some years ago. She had never suffered from indications of cardiac weakness; on the contrary, she was a strong, healthy woman, who was able to run races with complacency. In the early part of December, 1908, she had five teeth of the upper jaw removed by an unqualified person under a local anæsthetic made up of cocaine, iodine, and carbolic acid. The patient fainted during the operation, and alcohol and other restoratives had to be resorted to. Afterwards she complained of feeling faint, "shaky," cold, and of numbness. These symptoms continued during the journey home, and there was a sense of suffocation, and the patient volunteered the information that she "could not properly feel her feet as she was going along." She was put to bed, but still complained of feeling faint and seemed not fully conscious. Hot bottles and flannels were applied to the legs. During the night she vomited. She had an appointment with the operator for 10 A.M. the following day, but felt so ill that she was unable to reach there until about 4 o'clock. She told the operator of the symptoms already enumerated, but upon his assurance that it was all right, eleven teeth were extracted from the lower jaw under a local anæsthetic. The patient seemed to have quickly lost the power of speech and sight, and felt faint. During the journey home she also complained of a sense of suffocation, tremors, jerkings, and powerlessness of the limbs, loss of sensation of the legs, shortness of breath,

and great coldness. After reaching home she fainted, and her condition became apparently so grave that Dr. Leakey was sent for.

On reaching the patient about 9 P.M. she was found lying in a low chair, in an almost completely unconscious condition, extremely pale and cold, the skin moist and clammy, the breathing rapid and shallow, and the pupils dilated; the back was stiffened, there were tremors and muscular twitchings, and the knee-jerks and other reflexes were greatly exaggerated; there was no appreciable pulse at the wrist; the apex-beat was slightly outside the nipple line, very feeble, and somewhat irregular; no bruit was detected; the temperature was subnormal, and there had been some vomiting. Hot brandy, strychnine, digitalis, and aromatic spirit of ammonia were administered, and the patient was lifted into bed. During the night there were repeated syncopal attacks and other indications of grave cardiac failure. The next morning the pulse was rapid and extremely feeble. The coldness of the extremities continued for three days, by which time a faint mitral systolic bruit was audible.

At the end of a week the patient was allowed to sit up in bed, and a few days later was lifted on to a couch. She went out of doors for the first time on Jan. 18th, and commenced walking with support a few steps at a time. She complained much of sleeplessness, "started" on dropping off to sleep, and had very disagreeable dreams. In the fourth week, during a short walk one morning, she had a severe syncopal attack and had to be taken home in a bath chair. On examination she was found very collapsed and pallid, with an irregular pulse and evidences of dilatation of the left heart. During the night there were frequent syncopal attacks, and the following day her condition was considered so serious that Dr. Price was called in consultation. He found her with a pulse of 90 per minute, regular, exceedingly small and feeble, and of low tension; apex-beat outside the normal; a faint mitral systolic bruit audible; knee-jerks slightly exaggerated, and suggested the following treatment. Much light nourishing food, strychnine and digitalis (later iron and arsenic), hypnotics, to be kept flat in bed for a week, gradually sitting up during the second week, to be lifted out of bed the third week if progress satisfactory.

The patient was seen again in consultation on March 8th. Progress had been so slow that she had not been allowed out of bed until March 7th. She was very feeble; pulse 80 per minute, still extremely feeble and small, though better than on the last examination; apex beat rather outside normal position; advised to be kept in bed for a week. She was carried into the next room on March 14th, and walked there on the 31st. A third consultation was held on that day, when the pulse was found to be somewhat stronger and fuller. The patient had suffered from constipation, and complained of a feeling of great weakness after the administration of aperients. Altogether the progress was very slow. On April 25th she went out for the first time again in a bath-chair. She began to walk on May 15th. It was not considered advisable to let her go home to Leicestershire until July 29th. On Oct. 26th she only complained of a feeling of exhaustion after considerable exertion, and of irritability on slight provocation. The pulse was then much larger and stronger, but still not quite up to the normal; there was a very faint localised mitral systolic bruit.

In our view it is beyond doubt that the case was one of cocaine poisoning and that the symptoms of the first two days were typical of that condition in its acute form—on the first day in a comparatively mild degree, and on the second in an alarming degree, when a fatal termination was very narrowly escaped. We believe that the heart muscle was severely damaged by the poison, and that this accounts for the subsequent slow progress and serious relapse. In our judgment it is a matter of very grave concern that according to the present state of the law it is permissible that anyone without a medical training necessitating an adequate acquaintance with the physiological effects, proper dosage, and poisonous manifestations of cocaine may administer this drug as a local anæsthetic. We think the operator should have possessed the knowledge that the symptoms of the 24 hours following the first extractions enumerated by the patient and her sister were certainly those of a comparatively mild degree of acute cocaine poisoning, in which case he would no doubt have adopted proper precautions, instead of which he admittedly administered a larger quantity of the drug.

# TWO UNCOMMON FORMS OF DEFORMITY OF THE FEMALE GENERATIVE ORGANS, ONE CAUSING SYMPTOMS SIMULATING INTESTINAL OBSTRUCTION.

BY JOHN A. C. MACEWEN, M.B., B.SC. GLASG., F.R.F.P.S. GLASG.,

SENIOR ASSISTANT TO THE REGIUS PROFESSOR OF SURGERY, UNIVERSITY OF GLASGOW; SURGEON TO THE ELDER HOSPITAL, GOVAN; ASSISTANT SURGEON, GLASGOW ROYAL INFIRMARY.

CASE 1. *Absence of body of uterus and right appendages; presence of myoma and calcified dermoid.*—A married woman, aged 46 years, was admitted to the Royal Infirmary under my care when acting for Mr. P. Paterson on Sept. 21st, 1909, suffering from symptoms pointing to intestinal obstruction. A year previous to admission she had an attack of colic which lasted for a few days. On the present occasion a much more severe attack of colic came on two days prior to admission, the pain being referred principally to the umbilicus. Vomiting occurred twice on the first day of the present illness, while the bowels moved twice on the day previous to admission. Since then the bowels had not moved, nor had flatus been passed, notwithstanding frequent doses of castor oil and the administration of enemata. Blood had never been passed per rectum. There was frequency of micturition. The climacteric had occurred two years previously.

On admission the pain had become less severe, the temperature was 102° F., and the pulse 130, irregular, thready, and feeble. The abdomen was distended and tender to palpation, particularly over the left iliac fossa, where a large mass was easily detected on palpation, which was dull to percussion. Its mobility could not be tested owing to tenderness and abdominal rigidity. On vaginal examination the cervix was found to be normal in position and direction, but small and ill-developed. The uterine sound could not be introduced into the canal, but an ordinary probe went in for about an inch. The fundus could not be detected. The vaginal roof on the left side was occupied by a mass which was tender to palpation, while on the right side a hard rounded mass was detected which projected towards the rectum, and was easily felt on rectal examination. This mass was of about the size of a golf ball and was fixed.

Two enemata were given, but without result, and operation was decided upon. A median vertical incision was made below the umbilicus; the peritoneal cavity was opened and a quantity of sanguineous fluid was evacuated. A large tumour, subsequently ascertained to be fibromyomatous, at once presented. This tumour, roughly spherical in shape, and fully 5 inches in length, was freely moveable, being attached to a pedicle, also some 5 inches long, which had become twisted and was partially gangrenous. The pedicle was ligatured down close to what was supposed to be the serous surface of the uterus, and the tumour removed. The left Fallopian tube was also in a gangrenous condition and was also removed. The left ovary appeared normal but of small size. While this tumour doubtless accounted for many of the symptoms it did not explain the condition felt per rectum, and on passing the finger down along the course of the rectum a mass was now detected. On placing the patient in the Trendelenburg position and examining the parts it was found that there was no uterine body present, the peritoneum being reflected from the rectum on to the bladder much as in the male, save that on the left side there was an ill-developed broad ligament, with the gangrenous tube already mentioned, and fairly normal ovary. On the right side the appendages appeared to be entirely wanting, while a little to the right of the normal position of the uterus the hard mass referred to presented. The pelvic peritoneum, together with a subjacent layer of fibrous tissue overlying the tumour, was now incised and a portion of what appeared to be bone presented, which emitted a slightly hollow note when tapped. As my assistant said, the mass resembled a very small, well-ossified fœtal head. Endeavours were made to remove the mass, which, after considerable difficulty, was shelled out, and was found to consist of a roughly spherical shell of osseous matter (Fig. 1), which contained an oily material at

first sight resembling pus. No hairs, teeth, or other tissue elements were present. This wound was packed for 48 hours, and the patient made an uninterrupted recovery save for slight transient jaundice for a few days after operation.

The intestinal obstruction in this case was probably due to the pressure of the fibromyoma on the bowel, but no evidence was obtained of any portion being damaged thereby. While the calcified dermoid certainly projected into the rectum, it must have done so for a considerable period previously, and hence its influence may probably be discounted.

It is interesting to note that this woman, according to her statement, had menstruated regularly. She was married, but naturally had no family. The presence of ovary and tube on the left side, albeit small, would probably account for the regular menstruation. Did the fibromyoma, which on section was perfectly solid and hard, with its pedicle represent the muscular substance of the uterine body which had begun to enlarge after the climacteric, and did the dermoid represent the right ovary? (Fig. 2.)

CASE 2. *Absence of the lower end of the vagina.*—A girl, 16 years of age, was admitted to the Royal Infirmary on Sept. 8th, 1908, suffering from what was diagnosed as appendicitis with abscess. Three days prior to admission she was suddenly seized with severe colicky pain referred to the umbilicus at first, but which later became located over the right iliac region. This pain was practically constant, and she was given morphia for its relief. She had a somewhat similar attack two months previously, which, however, was less severe, and lasted only for a few hours. On her way to hospital she vomited twice.

On admission the temperature was 99·2° F. and the pulse 120. The abdomen generally was not distended, but there was a distinct tumour mass in the right iliac region which was not only easily palpable, but visible. The abdomen in his region was rigid and the mass very tender to palpation. Percussion over the mass gave a dull note. The bowels had moved regularly, and the tongue was clean. Menstruation had not yet begun. A rectal examination revealed a large fluctuant swelling on the right side, a wave of fluctuation being transmissible from the rectum to the swelling in the iliac fossa. There was no swelling in the perineum, nor suggestion of abnormality from the appearance of the external genitals. A vaginal examination was not made.

On the morning following admission the temperature had fallen to 97°, while the pulse had risen to 140, and I was asked to see her. The pulse-temperature ratio being unsatisfactory, and the patient obviously suffering, it was determined to operate. Under chloroform the mass in the iliac region became, if possible, more obvious, while it retained its hardness to touch. On opening the abdomen a mass of omentum was found in front of the swelling, which had been crushed by the swelling against the abdominal wall, and had become gangrenous from ischæmia. This mass was removed and the subjacent swelling investigated. It was immediately recognised to be the uterine fundus, which was pushed up against the omentum and abdominal wall by an enormously distended vagina. A finger was now introduced from the vulva into what appeared to be the vagina, but which was found to be a greatly enlarged urethra, the finger going straight and with the greatest ease into the bladder. Careful examination revealed the fact that there was no vaginal opening, there being only a greatly enlarged urethra, which expanded at its outlet to occupy the greater portion of the perineum, there being only a short interval between its lower border and the rectum. It was now seen that the case was probably one of retained menses arising, not from imperforate hymen, as is usually the case, but to entire absence of the lower portion of the vagina, and it became a question as to how the vagina might best be opened into without injury to the bowel. It was thought that, on applying pressure to the abdominal mass, a slight bulging of the posterior urethral wall high up took place, and accordingly an incision was made in the posterior urethral wall, about 1½ inches from the orifice, and, on deepening the incision, some two pints of dark fluid blood were evacuated, the abdominal swelling meanwhile subsiding. While the vagina was, of course, much distended, the uterus was small, but apparently normal. The opening into the vagina was now packed and the abdominal wound stitched up. The patient made an uninterrupted recovery, and has since menstruated regularly. Subsequent attempts by means of a plastic operation to narrow the urethra and widen the mouth of the vagina, and also to bring it to the surface, were only partially successful, and a further attempt is contemplated.

Probably two developmental factors were at work in this case. Normally the Müllerian

Diagrammatic representation of parts in the first case. A, Vagina laid open. B, Rudimentary cervix connected by pedicle to myoma (E). C, Dermoid replacing right appendages. D, Left appendages. E, Myoma replacing fundus uteri.

ducts open into the urogenital sinus about the end of the second month of intra-uterine life—the want of opening, therefore, would here date from a very early period of fœtal existence. Further, the fused Müllerian ducts open normally into the urogenital canal some distance from the surface, and only reach the surface by shortening of the sinus. In this case the shortening did not occur, and the patient was thus left with a large "urogenital" urethra, the vagina ending blindly about 1½ inches from the normal position of its orifice (Fig. 3).

FIG. 3.

Diagrammatic representation of the parts in the second case. A, Uterus projected against abdominal wall by distended vagina, which ends blindly in pelvis. B, Omentum crushed by uterus against abdominal wall and rendered ischæmic and gangrenous. C, Symphysis with bladder above and behind it. D, Rectum. E, Abnormally large urethra expanding to occupy whole vulvar orifice.

It will be seen that Case 1 presented symptoms suggesting intestinal obstruction from internal strangulation, while Case 2 resembled a case of appendicitis with a large abscess occupying the pelvis and pointing through the abdominal wall. In the first case the twisting and gangrene of the pedicle of the myoma probably gave rise to the temperature and pulse symptoms, while in the second the gangrenous omentum probably fulfilled a like function. Apart, however, from the confusion of symptoms presented, the writer ventures to think that the cases are in themselves of sufficient interest and rarity to justify their being recorded.

Glasgow.

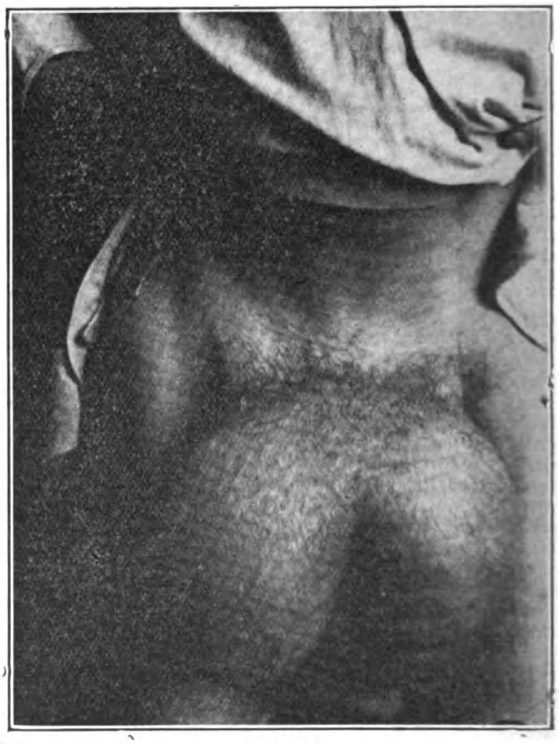
## NUCHAL LIPOMATA IN THE LOWER ANIMALS.

BY SIR JONATHAN HUTCHINSON, F.R.C.S. ENG.,
CONSULTING SURGEON TO THE LONDON HOSPITAL, HOSPITAL FOR DISEASES OF THE SKIN, BLACKFRIARS, ETC.

THE following note may be regarded as a kind of appendix to my article on Diffuse Lipoma published in THE LANCET of Nov. 26th, 1910, p. 1537. In that paper I advanced the opinion that what we have called the "diffuse lipoma" finds its principal form mainly in the male sex, and that it has its site in the fat which accumulates in certain regions around the roots of hair follicles. Its common position is at the back of the neck, and it might indeed be known as diffuse lipoma of the nape. In support of the statement that the fat which in this malady undergoes hypertrophy is that which imbeds the roots of large hairs I mention the facts that the region affected is that which in many animals grows the mane, and that in the human subject the same hypertrophy occasionally occurs in the pubic region around the roots of the large pubic hairs. In this latter position, although slight degrees of it are probably very common, examples sufficiently exaggerated to attract attention are probably rare. Still more infrequently are the matters of complaint brought under the attention of the surgeon.

I am now able to produce from a photograph one of these cases. It will be seen in the illustration that huge masses of fat are developed from the mons and adjacent parts, and are of such a size as completely to conceal the genitals. The patient was a man in whom very large masses had also developed on the nape of the neck and adjacent parts. Both from the nape and from the pubes the tumours were excised and were found to be huge masses of ill-defined fat developed immediately beneath the skin and closely adherent to it. The patient was a stout man in good health, but with no remarkable accumulations of fat in other parts than those named. It is the only case in which it was necessary to excise the pubic growths, and it affords proof that there is tendency in the same direction in these two regions.

It will be remarked at once that there is very seldom in the human subject any very marked tendency to the growth of large hairs in the back of the neck, and the next point I wish to establish is that certain animals in which a mane is present in this region there is a liability to fat hypertrophy about the roots of its hairs. Slight forms of this are, I believe, not very unusual, although I am not aware that any account of them has ever been published. My own experience is almost limited to asses, and at present I have under observation in two asses owned by two neighbours very remarkable examples of them. In the ass the overgrowth of fat begins at the root of the mane, and constitutes in slight forms and



Masses of fat in pubic region.

in all early stages simply a thick neck. Although placed mainly in the middle line there are, it may be observed, evidences of some central demarcation into two parallel masses which run side by side from the nape of the neck to the top of the withers. As the masses increase and become welded in one they tend to sway the mane over to one or other side. In one of the two asses mentioned above the mane is carried over by its roots to the right side, and is made to some extent irregularly pendulous. The tumours are never painful and usually the animal appears to be pleased to have them handled or rubbed.

Two points of interest must be mentioned. In the human subject these nuchal diffuse lipomata are met with, I believe, almost solely in males of middle age, and in those accustomed to drink malt liquor. The evidence given was that the patients were exceedingly fond of it, but it was not thought that they had any opportunity of over-indulgence.

I have no doubt that sex as well as habits of diet have something to say in the production of these hypertrophies, and especially with their location. In several instances in the human subject I have witnessed definite subsidence of the tumours as the result of abstinence, and conversely a few weeks of beer-drinking will cause the tumours very perceptibly to increase.

In the ass I have not as yet met with them in the female subject, and, curiously, those in which I have seen the tumours were castrated males. They were both well-conditioned animals and had been well fed and not overworked.

Anyone specially interested in this subject can have an opportunity for examining the asses I have mentioned by a visit to Haslemere (after due notice and by appointment).

Chenies-street, W.C.

# CLINICAL ASPECTS OF SOME VARIETIES OF EXCITEMENT.

BY W. T. MUNRO, M.B., CH.B. ST. AND.,
ASSISTANT MEDICAL OFFICER, ARGYLL AND BUTE DISTRICT ASYLUM, LOCHGILPHEAD.

THERE are numerous conditions of acute mania, or of delirium, with which one comes in contact in the work of a mental hospital, and many of these cases can be separated and differentiated and referred to a particular form of insanity. Perhaps most patients with any maniacal or excited condition (with the exception of acute alcoholic excitement), when certified, are looked on by the medical man as cases of mania. The object of this short paper is to try to give some points in the diagnosis which will help the general practitioner to form an accurate diagnosis and place his maniacal patients in the correct group of cases.

We have states of (1) mental exaltation or mania proper; (2) alcoholic excitement or delirium tremens; (3) excitement in general paralysis; (4) katatonic excitement; (5) semi-conscious epileptic states; and (6) excitement in dementia præcox. Let us look at such patients, and I will try to illustrate cases to give the differential points for an accurate diagnosis.

Perhaps the most common are those who suffer from acute alcoholic excitement. The general symptoms may be well known, but I give a case.

CASE 1.—Man, aged 42 years, admitted Jan. 17th, 1911. He was very restless and excited, but one could retain his attention for a minute or two, and on asking him where he came from he could tell us. He could also tell us what he did, and admitted that he had been drinking very heavily since the new year. He did not know where he was, and although he had been admitted only half an hour before examination he thought he had been here for a few days. Restlessness was extreme. He would lie still for perhaps two minutes, then would suddenly jump up as if he feared something. Again on lying quiet he would follow with his finger all round the walls and ceiling again to jump up suddenly. On asking him what he saw he described them as devils and dragons, and said he could not catch them. He was also very incoherent in his speech. He seemed to be apprehensive and to fear something. If shown anything such as a thread on his bed he lay and looked at it for a minute or two and then made a grab at it. He would also suddenly grab at the blankets at if he wanted to catch something. He was very tremulous, and his outspread fingers showed strong jerky tremors. His tongue was thickly furred and tremulous. His temperature was 100° F. and his pulse rapid. Knee-jerks were exaggerated; pupils were normal. There was a slightly dilated heart.

Now to examine the case. The patient is collected to a certain extent, but he has no idea of place or time. He can tell us what he does and where he comes from, but he does not know where he is or how long he has been here. Again, there are most vivid hallucinations of sight and continued restlessness, and the physical examination. The diagnostic features are the following: The tremor, the restlessness, the vivid character of the hallucinations of sight, the want of clearness of ideas of time and place with other signs of collectedness; and the physical features, such as temperature, pulse, slight enlargement of the heart, and exaggerated knee-jerks, are very common.

After an interval of four days the patient has recovered; he has lost 6 lb. in that time, but has gained 12 lb. since.

The next delirious condition which I wish to mention is the following:—

CASE 2.—A man, aged 39 years, was admitted on Nov. 2nd, 1910. When admitted he greeted me as an old friend and at once asked me to go to London with him. The history previous to admission was that the night before he had suddenly become unmanageable, threatening to kill his wife and children. He denuded himself, declaring that the voice of God had come to him telling him to remain nude till the Day of Judgment, and he threatened to kill anyone who came near him. Previous to that he had been perfectly well and working every day. He was put to bed but was very restless, tossing about in bed, wanting to get up, throwing the bed-clothes about him, while his movements were very tremulous. Then he would sit up and talk to himself in a most silly manner. On being spoken to he would be roused to attention for about a minute, and he told us where he came from, that he was a grand singer, and that when he sang the whole world heard him. He was very divertible; jumped from one subject to another at once. He was only to be here for a night, when Lady —— was coming for him in a flying ship. The night after admission he became violent, jumped up suddenly, attempted to jump out by the window, and cut himself slightly; then he said he was very foolish to have done so. Like Case 1, he seemed to be very apprehensive. He is also very tremulous. He tells us he sees a motor-car coming for him, then he sees Lady ——'s flying machine.

Now there are certain features which are much like Case 1. There is the tremor, the uncertainty of movement, the continued restlessness, the apprehension, and the hallucinations. Now with only the above features, and if these were not carefully noted, one might go wrong, but there are certain deviations from the picture of Case 1. Our patient is more confused and he has the most impossible delusions, while he has not the exceedingly vivid hallucinations of vision. To examine our patient further, one would notice at once that his speech was slow, syllabic, and slurring. His pupils were unequal, but reacted to accommodation, and, slightly, to light. There is no expression in his face. His tongue is tremulous, the knee-jerks are markedly exaggerated, no ankle clonus. Babinski positive, and he has a psoriasis all over his body. It is a case of general paralysis, and now we see there was nothing remarkable in his delusion that when he sang the whole world heard him. Question him further he tells us the church he sings in is his own and is painted in all the colours known. Moreover, he is very wealthy. As to causation, he has been a sailor, sailed to St. Malo and Dunkirk, but there is no evidence of specific infection.

What are the diagnostic features? We have the delusions of grandeur, the divertibility, the rapid change from one subject to another, the change of consciousness of personality, the motor symptoms, the tremor, the unequal pupils, and, on physical examination, the condition of the reflexes.

The third patient whose condition I wish to describe is, perhaps, more interesting than either of the two previous cases:—

CASE 3.—Woman, aged 27 years, a tinker. She also exhibits several features which might easily be spoken of as acute mania. Her excitement is only paroxysmal, but if seen during that stage, and only then, and not carefully examined a wrong diagnosis might easily be made.

Our patient's excitement is best seen just after meals. First, she will not start to eat anything whilst the others are at their food. Now try to take away her food—she resists. Trying to persuade her to take her food makes no difference. She will not even look up. Her face is expressionless; then try to remove her food, she resists and becomes very excited.

She calls out "Oh God! Oh God!" repeating herself several times, will clutch bread in her hands, and resist all effort to remove it. She now becomes abusive, swears at one badly, and will tear one with her fingers. You speak to her, she repeats what you say over and over again, to again become very abusive. During this stage she may attack the nurse, and does so with great cunning. Now leave her alone, she will lie back with her food, but still talks angrily, repeating herself again and again. In a short time she is quiet, and one would notice that she lies rigidly in one position. Now to note the condition as far as we have seen. There is excitement, but there is more. The perception of

the patient is perfect. Is not the condition negativism? There is first the attempt to persuade her to eat, and she never gives you any indication that she has heard you, but lies quiet; no words from her, but she will not eat. Now try to remove her food, again she is negative; and this time there is the excitement with also a repetition of phrases.

Further, a pin can be stuck into this patient's forehead and she will not wince, and if we lift an arm it remains in the position we put it into for about a minute, and gradually falls down. I have pointed out the negativism: Why is she negative? Is it from any delusion or apprehension? It cannot be from either. There is nothing in the behaviour of the patient to suggest that there is any apprehension or delusion. Again, why should she not wince when a needle is pushed into her forehead, and become excited when a gentle hand is put on her? Clearly we have to deal with a case of negativism, an instinctive opposition without foundation from delusion or apprehension.

My diagnosis is katatonic excitement. We have as diagnostic features the abrupt alternation between senseless excitement and rigid tension, the taking up of peculiar attitudes, the confusion of talk with complete comprehension, the meaningless repetition of the same words.

The next patient I wish to mention shows a condition of apprehension.

CASE 4.—Woman, aged 50 years, for the past fortnight has shown a condition of terrified apprehension. She is very excited, and every time one goes near her she calls out with a frightened look, "Oh God! Oh God! it was not me," repeating this over and over again. She varies her words "You won't do it," "I did not do it," "Why am I put here?" Then she will catch hold of you and implore you "Don't leave me," "I did not do it." Again, if I spoke to the nurse, she complained that we were speaking about her and making up our minds what we should do with her. She could easily hear what was said to the nurse, but she did not appear to understand what was said. Clearly, she is in a state of terrified apprehension. You speak to her and ask what is the matter; you cannot get any answer. She still continues in the same excited, apprehensive state, and she does not understand what is said to her. There is more or less stupor. There are features like Case 3. There is the meaningless repetition of words with excitement, but there is a great distinguishing feature in the fact that the patient is stupefied. Now again our patient is very restless, she is not in bed and she will not sit still any longer than a minute, but gets up and moves from one place to another. There is great uncertainty in her movements and she even hits out at times. This condition of seeming ignoring of questions is not negativism. She is stupefied. Again, she is quiet for, perhaps, a minute, and you can move her arms about without any hindrance from her own will. Her excitement is meaningless and her assaults are without the adroitness of Case 3. Her talk is very disconnected, but, unlike Case 3, it is comprehensive in that the whole talk is due to apprehension. The condition is a dream-like one, with changing incidents and fluctuations of emotions of an apprehensive nature and utterances in accord.

Consider the case. Here again we have excitement or delirium. What are we to eliminate? We may exclude the alcoholic form on account of the profound stupefaction, also from the want of tremor and the want of the vivid hallucinations of vision. Alcoholics are not nearly so stupefied. You can arouse them to answer you and even to give a correct answer. They are collected to a certain extent. The clouding of consciousness is too deep for ordinary fever delirium. Exclude katatonic excitement by the want of perception and hence no negativism. Again, we do not have the repetition of phrases and abuse of katatonia, nor do we have the alteration between senseless excitement and rigid tension. Our patient's excitement is continuous. Clearly we have a condition of delirium the result of an apprehensive state of mind. We have profound disturbance of comprehension, active delirium, extreme apprehension, an inclination to reckless acts of violence, and the condition of stupor along with excitement corresponds to certain epileptic semi-conscious states. The only thing else noteworthy is the condition of the pupils. They are dilated and react very feebly to light.

This patient has now recovered and does not remember anything at all about her condition, but says she must have been very ill. There is little doubt that the condition is an epileptic one. In this patient we actually have a history of fits. But apart from fits we have irritability and real bad temper just before this semi-conscious epileptic state. A typical feature of epileptics is piety alternating with irritability. At the time of writing our patient is reading the Bible.

My next patient is more impulsive. Like all the previous cases, she is subject to outbursts of excitement, and she exhibits some features which are different from them all.

CASE 5.—Woman, aged 28 years, up to a few days ago had remained very quiet, but has now reached a state of excitement. She chatters in a confused way—really a senseless playing with words. She runs about the ward, moving from place to place, is very impulsive, apt to do most reckless things, will push her fist through the window, will smash dishes, and has attacked a nurse. She is very abusive, and grimaces, making most hideous faces.

As far as we have seen, the most outstanding features are the impulsiveness and the grimacing. She is quite collected. If you ask her questions she answers only in monosyllables, and very slowly. In a short time her outburst of excitement is over and she sits down, and the most significant feature which will be observed is a vacant, silly smile. There is difficulty in getting her to start to do any work, and when she does anything one would notice that her movements are languid and listless. There is a great want of initiative, but there is no hindrance of will to action, only there is the want of interest, everything is done in such a dull, listless manner. Another feature about our patient which is noteworthy is the loss of interest in her surroundings. She does not care where she is put or who looks after her. She has no emotions. She expresses no desire, has no hopes and no fears.

Now what is the diagnosis in such a patient? We have seen her excitement, which is only temporary, her recklessness and her restlessness, but these features have little to do with the diagnosis. To consider our patient. Her ability to understand what is said to her is unimpaired, but she only answers in monosyllables. Again, there is the great want of emotion, or, as it has been put by Kraepelin, a want of the strong feelings of the impressions of life. The diagnosis is dementia præcox.

The features of such a case are: the want of feeling of the impressions of life as seen in the want of the emotions. Her lack of interest in her surroundings with ability to understand and remember. Again, the vacant, silly smile and the grimacing are common, as is also the great want of initiative.

The five cases which I have ventured to describe all show varying features, and each of them is worth consideration. One might take exception to classifying katatonia and dementia præcox separately, as katatonic symptoms are common enough in dementia præcox, but my intention was to describe katatonic excitement separately, and its significant features will justify a special description.

CASE 6.—Alongside of these five cases, and for comparison I shall illustrate the special features of a married woman, aged 32 years, who exhibits great mental exaltation and can be called a true case of mania, properly so called. As soon as one enters the ward the following picture may be seen. She is very noisy and excited. She is walking about the ward; is attracted by the least thing, will pick up anything, remark upon it, and throw it away at once. Perhaps she is induced to sit down, but the moment you turn your back she is up again, attracted by something else. Now she will seize a chair, swing it round and sit down on it, to get up again immediately and go through some other movement. All this time she is talking, but one could not follow the purport of her talk as she changes so often from one thing to another.

She is very fond of dress, and perchance in her wandering round the ward she sees herself in a mirror and she will stand for a minute and admire herself. Her own image has attracted her attention. I once saw her steal a nurse's cuffs, put them on, and sit down as "my lady" quite quiet for about a minute. You speak to her, ask her name, and she will give a correct answer, but she answers so much more, and at once gets away from one subject to another—speaks and does just whatever comes to her mind. You cannot fix her attention on one subject; she cannot be led into any connected conversation, digresses immediately, and then jumps up and moves round the ward as previously described. She is very merry, she laughs throughout her talk, and when out for her walks goes round singing all sorts

of songs, and will sing during the whole time out. Our patient's merriment may very soon change to angry irritation. She becomes very abusive and, as the impulse moves her, will attack any one, and it requires considerable restraint to prevent her doing damage.

What are the significant features of our patient? The most prominent is the divertibility. Some accidental attraction at once arrests her attention, but this is immediately thrown out and some new attraction is forced into consciousness, to be at once departed from. This divertibility is shown equally in mood—merriment to anger; in thought—changing ideas; and in action—her continued changing of position and movements. The patient has not the ability to prevent herself being ruled in thought, mood, and action by the influences of the moment. Next one would note the "flight of ideas." Her thoughts are to no purpose. The train of thought is broken at once by one idea being driven out by another. Again we would note the impulsiveness, in the fact that she will attack anyone. Here we note the same thing: there is no check on the transposition of impulses of the will into action. We would also note the deficient attention. We cannot retain our patient's attention on any subject. The rapid change of the sensations which are forced into consciousness, and each in turn receiving attention, makes it impossible for her to concentrate her mind on any subject.

The whole condition may be summed up thus:—There is no check on the number of ideas which force themselves into consciousness; no check on the sensations received, and each in turn may show itself in mood, action, or speech.

Looking at all those cases, what have we? There are certain features different in them all. First take attention. Case 1 can attend and can comprehend what is said to him to a certain extent, but is soon taken up with his hallucinations of sight. Case 2 can be aroused to attention, but is more confused than Case 1, and soon mentions his delusions of grandeur. Case 3 understands what is said to her, can attend, but will not let you see she does attend, except in the fact that she is negative. Case 4 is stupefied and cannot attend. Case 5 can attend, but she has no interest in what is said to her; she is languid and listless, and would rather not be troubled. Case 6 cannot attend on account of the divertibility; the rapid change of the sensations forced into consciousness and then put into action.

All our cases showed excitement, but all have showed some points of distinction. It would only be taking up space were I to add a note about each, as to which had delusions, hallucinations, or as to the condition of the memory, &c. Enough will be got in the short commentary at the end of each case for an accurate diagnosis. My paper is only clinical, but it may serve a useful purpose if it stimulates a proper investigation into all cases of "Mania."

Lochgilphead.

# Clinical Notes:

## MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

### HYSTERECTOMY FOLLOWED BY DOUBLE PHLEBITIS.

BY H. MACNAUGHTON-JONES, M.D. R.U.I., F.R.C S. IREL. & EDIN.,
PRESIDENT OF THE OBSTETRICAL AND GYNÆCOLOGICAL SECTION OF THE ROYAL SOCIETY OF MEDICINE.

THE patient, aged 48 years, a nullipara, had suffered for some years from severe hæmorrhages, for which she had been curetted a few years previously. At the time of operation for tumour of the uterus she was greatly emaciated and extremely anæmic, and altogether in a most unfavourable condition for operation. The tumour was delivered with great difficulty, being firmly wedged in the pelvic cavity. It was a multinucleated myoma, one mass of isolated nodules from cervix to fundus. On the fifth day after operation proctoclysis was commenced, and as there was some distension of the abdomen the wound was opened and a suprapubic drain inserted. Exploration revealed nothing, and only some serous fluid escaped. The proctoclysis was continued on and off for five days, but the suprapubic opening was not closed for ten days. The first symptoms of phlebitis appeared in the left femoral region on the thirteenth day after operation, and the swelling extended to the entire limb. It had returned to its normal size by the twenty-fifth day. On the thirtieth day the right thigh commenced to swell, and it followed the same course as the left, becoming the more swollen of the two. The swelling subsided completely in about ten days, and from that time there were no untoward symptoms. The patient has since done well.

This is the only instance of phlebitis in both legs as a post-operative complication that I have been confronted with. The important lesson to be learnt from the case—and one that is often overlooked—is the increased risk run from grave anæmia, the result of bleeding from fibroids, and also the unfavourable conditions consequent upon this complication which increase the operative mortality. Whatever be the precise physiological cause or causes, there is no doubt that the condition of the blood in such cases tends to thrombosis; also the possible effect of traumatism in the forcible delivery of these tightly wedged pelvic tumours has to be remembered.

As generally occurs, the left leg was the one first affected, and it was rather remarkable that the attack in the right did not begin until the thirtieth day after operation. In Kelly's "Operative Gynæcology" (1898 edition) it is stated that out of some 1100 operations he had had phlebitis in both legs in only one instance, and in his last classical work on medical gynæcology, written with Noble, the authors state that out of 7130 women operated upon thrombosis occurred in 48. Of these, 727 had fibroid tumours, and 19 of the 48 cases resulted from operations on fibroid, a relation regarding the greater risk of thrombosis from fibroids which is in accord with the experience of other surgeons.

The therapeutic points of interest in the case were the good results following the proctoclysis with suprapubic drainage, as recommended by Dr. J. B. Murphy, and the benefit obtained on two occasions when the bowel was obstinate from subcutaneous injections of infundibulin—"pituitary extract." It may also be interesting to note that in this, as in other cases in which I have had to deal with extreme anæmia, the patient was kept on "carnine," in the present instance for 17 days, in addition to other nourishment.

Harley-street, W.

### NOTE ON A CASE OF PANCREATIC CYST IN A CHILD AGED 14 MONTHS.

BY D. I. CONNOLLY, M.B., CH.B. VICT.,
ASSISTANT RESIDENT MEDICAL OFFICER, CRUMPSALL WORKHOUSE, MANCHESTER; LATE ASSISTANT HOUSE SURGEON, STAFFORDSHIRE GENERAL INFIRMARY, STAFFORD; LATE HOUSE SURGEON, ST. MARY'S HOSPITALS FOR WOMEN AND CHILDREN, MANCHESTER.

THE patient was admitted into the Staffordshire General Infirmary on Jan. 29th, 1910. The history, as given by the mother, was as follows. The child had been breast-fed up to about the age of 10 months, when she was weaned. She had not had a day's illness up to three or four days before admission to hospital. The mother then noticed that the child became listless and refused food, also that diarrhœa set in. At the same time the little one developed difficulty in swallowing, apparently having a "sore-throat." The mother became alarmed at the child's condition, because, as she said, "she was always so lively and full of play," and brought her to hospital.

On admission the child looked fairly well-nourished, but wore an anxious expression, and was quite listless. The tongue was furred, the papillæ were prominent, and there was some injection of the fauces. Nothing was to be made out in the chest. On examining the abdomen, it was found to be distended and tympanitic all over. Palpation elicited a feeling of resistance in the right hypochondrium. The movements of the intestine were audible on auscultation. The pulse was rapid, reaching from 160 to 180 per minute, and the temperature at first was about 99° F. In the nervous system there was nothing of note except the general languor previously noticed. It was not found practicable to obtain a specimen of urine. There were no signs of rickets or any deformity.

Treatment consisted of milk only. The diarrhœa not improving, albumin water was substituted. Of drugs, grey

powder in half-grain doses twice a day was given; also a mixture containing 2½ grains of bicarbonate of sodium and ½ minim of tincture of nux vomica was administered every four hours. Later brandy in 10-minim doses every four hours was given. The fauces were irrigated regularly with weak boric acid lotion.

On the second day after admission slight jaundice supervened, the stools became clayey and more frequent, and curds were also prominent. The abdomen became more distended, and now a definite rounded tumour could plainly be made out in the right hypochondrium. It had a convex border directed downwards. The mass was felt to extend across the middle line and to reach into the left hypochondrium. It was dull on percussion. A peculiar fact was noticed, that on firm pressure over the swelling an evacuation of the bowels ensued. On the fourth day the jaundice deepened considerably, diarrhœa was still frequent, and the stools continued quite clayey. The temperature rose to 102·8° on the evening of the second day and continued to vary between 100° and 104°, but mostly above 102°, until the afternoon of the ninth day after admission, when it fell to 99°, and on the morning of Feb. 8th (the tenth day) to 97°, when the patient died. The pulse kept somewhere about 160 to 170 beats per minute, till the eighth day, when it dropped by degrees from 176 to 114 per minute.

*Post-mortem examination.*—The thoracic cavity was considerably encroached upon owing to the pushing upwards of the diaphragm by the liver. There was no fluid in the chest; all its viscera were healthy. On opening the abdomen the liver was found to be displaced, so that its visceral surface looked more forwards than downwards and its lower edge reached posteriorly almost to the crest of the ilium. It was bile-stained, but otherwise healthy. The gall-bladder was enlarged and contained bile. A large fluctuant mass was found pushing forwards the posterior peritoneum and intestines. The duodenum and first part of the jejunum were adherent to the surface of the tumour and spread over it. The whole of the abdominal viscera were removed *en bloc*. The kidneys were normal except that they were bile-stained. The spleen was unaffected. There was an accessory spleen present. The fluctuant mass was found to be a cyst arising from the head of the pancreas, the main portion of pancreatic tissue having disappeared; part of the tail of the organ, however, still remained. What appeared to be soft glands were found along the abdominal aorta; they resembled also small masses of fat somewhat similar to appendices epiploicæ. The tumour, by its mechanical effects, had caused a complete obstruction to the bile flow; hence the symptoms and cause of death. The cyst contents were not examined. There was no examination of the head. The pelvic viscera were normal, as was also the stomach.

I sent a report of the case to Professor J. Lorrain Smith, who very kindly looked up the literature bearing on the subject, and he said that, so far as he had gone, the case seemed to be unique. The specimen is now in the museum of the Pathological Department of the Victoria University, Manchester. I have no comments to make on the case, being content with recording the facts and leaving explanations and theories of causation to more capable hands.

I am indebted to Dr. C. Reid, senior physician of the Staffordshire General Infirmary, for leave to publish the notes of this case, and I also wish to thank Professor Lorrain Smith for the trouble he took in looking up the literature of the subject.

Manchester.

THE LIVERPOOL EYE AND EAR INFIRMARY: THREATENED CLOSURE OF WARDS THROUGH LACK OF FUNDS.—At the ninety-first annual meeting of the trustees of the Liverpool Eye and Ear Infirmary, held on March 13th in the town hall, the Lord Mayor presiding, there were expressions of profound regret at the unsatisfactory state of the finances of the hospital. The deficit on the accounts now amounts to £3246. The committee stated that the only way it could see of making a sufficient reduction in expenditure was to close the upper wards (30 beds), which would be a great calamity. The Lord Mayor, the Archdeacon of Liverpool, and other speakers deplored the paucity of support, and voiced fervent hopes that the public, who receive such benefits from the infirmary, would adequately contribute to its funds. Another wail lay in the paucity of the attendance at the meeting.

### SURGICAL SECTION.

*Myositis Ossificans.—Femoral Hernia.—Congenital Pouch of Bladder.*

A MEETING of this section was held on March 14th, Mr. RICKMAN J. GODLEE, the President, being in the chair.

The three following papers were read and are published in full in this issue:—The PRESIDENT: Myositis Ossificans Traumatica (p. 791); Mr. G. H. MAKINS: Traumatic Myositis Ossificans (p. 792); and Mr. A. A. BOWLBY: The Formation of Bone in Periosteum Separated by Injury (p. 793).

Mr. C. H. FAGGE read a paper on the Inguinal Method of Radical Cure for Femoral Hernia. He said that he would like to make a few practical remarks about the details of Lotheissen's operation, which appeared to him to be of first importance. Owing to the presence of the cord it was undoubtedly more difficult in the male than in the female, but it was relatively of greater value in strangulated than in other cases owing to the ease with which the imprisoned coils could be manipulated in full view and carefully examined before they were returned. Gimbernat's ligament might when necessary be divided. Outside the sac from above an abnormal obturator artery could be seen and avoided. The sac could usually be dragged bodily upwards out of the femoral canal after it had been opened and its contents returned; in freeing that the deep epigastric vein had to be defined and avoided; it was not until his thirty-second case that he injured that vessel and was compelled to ligature it after some annoying hæmorrhage. After ligaturing the sac and allowing its stump to retract upwards the divided edges of the parietal abdominal fasciæ (transversalis and iliac) might with advantage be brought together over the sac by interrupted catgut sutures. Three or four interrupted sutures were necessary for the approximation of the conjoint tendon and Cooper's ligament after free definition of the latter; in passing those sutures lay the chief difficulty of the operation. The outermost must be passed through the Cooper's ligament just behind the inner border of the femoral vein, which required full and careful refraction; it would be found easier to pass those mattress sutures first through Cooper's ligament and to tie them above rather than below, a half-circle cutting needle being used, while the peritoneum and bladder were protected with flat retractors. He had been accustomed to use iodised catgut throughout. He had not seen any evidence of compression of the femoral vein by those sutures, but one of his cases, otherwise successful, had developed a saphena varix.

Mr. JAMES BERRY read a paper on a Large Congenital Diverticulum of the Bladder treated by Resection. The patient was a labourer, aged 21 years, who was admitted to the Royal Free Hospital on Nov. 18th, 1904, complaining of recent hæmaturia. When examined under an anæsthetic a large, rounded, soft swelling was found in the right iliac fossa and extending thence up into the right loin. Although he had passed urine shortly before the examination, nevertheless as much as 37 oz. of urine were withdrawn by catheter. On March 5th, 1905, a long median incision was made through the lower abdominal wall and the bladder freely exposed. The bladder consisted of two nearly equal parts, each about as large as a normal bladder. The lower and anterior one occupied most of the true pelvis, and had a tough fibrous wall in which very little muscular tissue could be seen. The posterior sac had a very thick muscular wall, and lay above and behind the other. The anterior sac was then freely opened, and 41 oz. of fluid were withdrawn from it. A more or less triangular portion of the wall was left *in situ*, and all the rest of the sac was cut away. The patient made an excellent and uneventful recovery. He now informed Mr. Berry that he was in excellent health and had no urinary trouble at all. In the day-time he micturated every three or four hours, and he very rarely had to get up at night to do so. Mr. Berry ventured to record that case on account of its rarity, as he had not been able to find a precisely similar

one recorded elsewhere. Mr. John G. Pardoe had kindly drawn his (Mr. Berry's) attention to an excellent paper by Dr. Hugh H. Young of Baltimore[1] on the Operative Treatment of Vesical Diverticula, with report of four cases. A bibliography of the literature was given, together with a short account of the cases of excision of a diverticulum by Péan, Czerny, Riedel, Pagenstecher, and von Eiselsberg, besides his own three cases in which that method of treatment was adopted. The chief points of interest in the present case seemed to be the large size of the cyst; its congenital nature, shown by the existence of urinary symptoms in early childhood; the absence of any acquired obstruction in the urethra which would have led to the formation of such a pouch, and the opening of the left ureter into the pouch far away from the bladder; the dilatation of the left ureter, which was not due to any stricture at its vesical orifice, since a probe could be (and was) readily passed up into the ureter. It was apparently due to the absence of muscular fibre in the wall of the pouch into which the ureter opened, thus permitting the intravesical pressure during micturition to be transmitted directly to the ureter. The operation itself presented no difficulty of any importance.

## OBSTETRICAL AND GYNÆCOLOGICAL SECTION.

*Exhibition of Specimens.—Primary Abdominal Pregnancy in a Rabbit.—Hæmatocolpos.—Origin of Follicle Cells of Ovary.*

A MEETING of this section was held on March 2nd, Dr. H. MACNAUGHTON-JONES, the President, being in the chair.

Dr. EARDLEY L. HOLLAND exhibited a Sarcoma of the Uterus.

Dr. R. D. MAXWELL showed an Ovarian Cyst containing thyroid gland tissue.

The PRESIDENT exhibited a specimen consisting of a large retort-shaped Hydrosalpinx and a Cystic Ovary, with a peritoneal cyst behind the mesosalpinx. On removal the latter was found to be filled with a bright orange-coloured fluid; the ovarian cyst was a blood cyst, and the dilated fimbriated end of the hydrosalpinx was adherent to the ovary. He also showed a Multilobular Myoma of the Uterus removed from a patient aged 45 years. The operation was followed by attacks of phlebitis in both legs, the first on the thirteenth day after operation in the left femoral region, and that in the right leg on the thirtieth day after operation. The value of infundibulin (pituitary extract) was shown in this case when there was difficulty in moving the bowels. It was the only case of phlebitis of both legs which he had seen, and it exemplified the well-known risk of this complication in connexion with bleeding fibroids. The patient made a good recovery.—Dr. AMAND ROUTH, Mr. ALBAN DORAN, and Dr. A. E. GILES discussed the case, which is separately reported in this issue of THE LANCET.

Dr. W. BLAIR BELL read a short communication on Primary Abdominal Pregnancy in a Rabbit, in which it was pointed out that while secondary abdominal pregnancy, following rupture of the cornua, was fairly common in hares and rabbits, primary abdominal implantation had not previously been described. Owing to the frequency with which tubal or ovarian abortion or cornual rupture with secondary abdominal implantation had occurred without macroscopical evidence being obtained, it was insisted that no case could be accepted unless serial sections of the ovaries, tubes (and, in animals, of the uterine cornua) were made, however great the other evidence might be. In the case recorded in this paper of primary abdominal pregnancy in a rabbit, four full-term fœtuses were found in a tumour attached to the gastro-colic omentum. The specimen was shown, together with skiagrams of the specimen and of the young rabbits at birth. Sérial sections had been made of the ovaries, tubes, and uterine cornua, and no trace of the laceration could be found, nor was there any evidence of a recent intra-uterine pregnancy. Seven corpora lutea of the same age, and considered to correspond with the date of the abdominal pregnancy, were found, and shown in photomicrographs. The number of corpora lutea rather indicated coincidental intra-uterine pregnancy, for it was usual to find that the number of corpora lutea corresponded with the number of fœtuses, but, of course, after several months no histological evidence would be obtainable of changes in the uterus due to a previous pregnancy.—Dr. AMAND ROUTH cited cases by Dr. Pembrey and Dr. Bellingham Smith, and Mr. Bland-Sutton's opinion that there was no evidence of the occurrence of tubal pregnancy in the lower animals (except in one doubtful case in a baboon). He believed that all the recorded cases were subsequent to rupture of the uterus.

Dr. BLAIR BELL also read a paper on the Nature of the Fluid contained in a Hæmatocolpos. The histories of two cases of hæmatocolpos in girls, aged respectively 18 and 16 years, were recorded. In both there was a large fluctuating tumour reaching above the umbilicus, on the top of which was riding the undistended uterus. A third case, under the care of Dr. T. W. Eden, was also mentioned. A bacteriological examination of the chocolate-coloured fluid collected from the second and third cases showed it to be sterile. A full chemical examination of the fluid from the second and third cases gave the following results:—(*a*) It contained a very large proportion of mucin; (*b*) the pigment is mostly hæmoglobin, with a little methæmoglobin; (*c*) there is 90 per cent. of water and 10 per cent. of solids; (*d*) the nitrogen present amounts to 1·43 per cent., which is equivalent to 9 per cent. protein; (*e*) lactic acid is present in large quantities; (*f*) the calcium content is double that of normal blood; and (*g*) neither fibrin ferment nor fibrinogen could be detected.

Dr. A. LOUISE MCILROY read a paper on the Origin of the Follicle Cells of the Ovary, which was illustrated by many lantern slides and photographs.

## MEDICAL SOCIETY OF LONDON.

*Influence of Diabetes and Gout on Tuberculous Infections.—Influence of Syphilis on Tuberculous Infections.*

A MEETING of this society was held on March 13th, Mr. CHARTERS J. SYMONDS, the President, being in the chair.

Dr. NATHAN RAW read a paper on the Influence of Diabetes and Gout on the Tuberculous Infections of the Human Body. He said that diabetes and gout were both disorders of nutrition, each presenting symptoms of great dissimilarity. In diabetes the power of resisting microbic invasion was greatly diminished, whilst in gout it was decidedly increased. Physicians had long observed the intimate association of diabetes with tuberculosis and the tendency for pulmonary lesions of a tuberculous nature to supervene in the course of the disease. It was also well known that those persons who were disposed to acute attacks of gout were peculiarly immune to tuberculosis. His observations had been made as the result of a careful study of 62 cases of diabetes mellitus occurring in hospital and elsewhere during the last 12 years, including post-mortem examination of 27 cases. Of the total of 62 cases of diabetes, no fewer than 37, or 59 per cent., were affected with tuberculosis, chiefly the pulmonary form, only two patients having abdominal tubercle. A point of great interest was that on first examination only 11 patients had symptoms of pulmonary tuberculosis on admission to hospital (as far as could be detected); the remaining 26 patients developed the disease during the progress of the diabetes. A question of absorbing interest was, When did those diabetic patients receive the tuberculous infection? In the 26 patients who developed pulmonary lesions in hospital the infection could not have occurred there, as they were quite apart from such patients. He had long held the view that the great majority of cases of pulmonary and other forms of tuberculosis received the infection in the early years of life, and that the tubercle became encapsuled and quiescent for a varying length of time, only to come into activity about the period of adolescence. It might be that those persons who were predisposed to diabetes might be unusually susceptible to infection by tubercle bacilli, and that the increasing debility associated with diabetes favoured the rapid progress of a tuberculous infection. It was most rare for any case of pulmonary tuberculosis to develop diabetes. During the last 20 years he had had under his hospital care over 4000 cases of tuberculosis, and he could not recall a single instance (in whom the urine was sugar-free on admission) which developed diabetes mellitus. Gout was another mysterious disease of which they knew little. There could be little

[1] Johns Hopkins Hospital Reports, 1906, vol. xiii., p. 401.

doubt that changes in the blood were of the highest importance in determining an attack, and in his opinion the peculiar constitution of the blood plasma induced in some unknown way a high resistance to ordinary bacterial infection. It was unusual to meet with gout amongst the working classes, but exceptions did occur, and during the last 12 years he had had under his observation 27 patients who were admitted in the acute stages of the disease, and 24 had been seen in private patients. In not a single one of those patients had he been able to detect any trace of tuberculosis. He had, therefore, come to regard the gouty diathesis as antagonistic to tuberculosis. With a view to establishing the accuracy of the clinical experiment it occurred to him to observe the results of growing pure cultures of tubercle bacilli on media which had previously been mixed with blood from cases of diabetes and gout. After four weeks' incubation no growth was observed, and even after eight weeks there was only to be seen a slight irregular growth on the surface of the medium, without any distinct clumps of bacilli. A control experiment was made when the growth was luxurious and well marked in 14 days. Those examinations were repeated exactly with blood from another diabetic case and another gouty one, with precisely similar results. His conclusions from that work were: Diabetes predisposed to the development of tuberculosis; gout had an inhibitory effect on the growth of tubercle bacilli; the blood plasma was the determining factor in the growth or inhibition of bacterial infections within the human body.—A discussion followed in which Dr. F. DE HAVILLAND HALL and Dr. F. PARKES WEBER took part.

Mr. D'ARCY POWER read a paper on the Influence of Syphilis on Tuberculous Infections of the Human Body. He said there was a general belief that the tuberculous bore syphilis badly, but a little reflection showed that such a statement was too general to be of use, for the two diseases might occur under widely different conditions. Mr. Power divided his subject into:—A. Inherited syphilis: (1) a child with heredo-syphilis might acquire tubercle; (2) an adult with heredo-syphilis might become tuberculous. B. Acquired syphilis: (1) an adult with active tubercle might acquire syphilis; (2) an adult with acquired syphilis might become tuberculous late in life. That classification showed that syphilis and tubercle might be active at the same time and in the same individual; they might overlap or they might be widely separated in point of time. Each condition had its own prognosis and the results of the various combinations could not be summed up in a single sentence. The whole question was in need of elucidation, and he thought that valuable results would be obtained if medical men in general practice would record any observations which came under their personal notice. Formerly it was difficult to distinguish between syphilis and tubercle, but the advance of pathology now afforded scientific data in place of a clinical diagnosis. Mr. Power then read the notes of cases in which syphilis seemed to have prepared the way for tuberculous inflammation of the tongue and for tuberculous inflammation of the ankle. He also gave details of cases where acquired syphilis had acted upon tuberculous lesions, making them more active, and where tubercle attacking tissues late in life had been less destructive than usual owing to previous syphilitic changes. Mr. Power concluded his paper with the following propositions: 1. Children with heredo-syphilis often showed signs of tuberculous disease of the joints in the form of "gummatous" synovitis which did not improve beyond a certain point under treatment by antisyphilitic remedies. 2. In young adults born of syphilitic parents an attack of pneumonia or other infective disease might be followed by signs of syphilitic inflammation (syphilis hereditaria tarda). The syphilitic lesions thus manifested might become tuberculous and the patient might die from tuberculosis. 3. Adults who acquired syphilis whilst they were suffering from tubercle were liable to have any pre-existing tuberculous inflammations rendered much more active. It was to those persons that the generalisation applied "The tuberculous bore syphilis badly." 4. Old persons who acquired syphilis many years previously might be attacked by senile tuberculosis. The tuberculous inflammation ran a more chronic course than usual in such persons and there was less liability to suppuration.

After Dr. PARKES WEBER, Dr. DE HAVILLAND HALL, Mr. V. W. LOW, and Dr. RAW had spoken, Mr. D'ARCY POWER replied.

## OPHTHALMOLOGICAL SOCIETY.

*Three Cases of Optic Nerve Tumours.—A Morgagnian Cataract.—Granuloma of the Retina.—Exhibition of Cases and Specimens.*

A MEETING of this society was held on March 9th, Mr. G. A. BERRY, the President, being in the chair.

Dr. A. HILL GRIFFITH read a paper entitled "Three Cases of Optic Nerve Tumour," illustrated with a number of photographs and specimens. He said that two were specimens of intra-dural and one of extra-dural growth. In the first case there had been protrusion of the right eye for seven and a half years, and when seen the patient had marked forward displacement of the eyeball. Movements were good, except downwards. There was a lobulated swelling between the globe and the inferior edge of the orbit. Distinct resistance was encountered. Vision was J 16. The disc was pale and atrophic. At the operation the eyelids and entire contents of the orbit were removed by a circular incision, the eyebrow being preserved. The cavity was lightly packed with gauze. A month after the operation five Thiersch grafts from the patient's thigh were transplanted into the orbit. When seen recently the orbital cavity was well lined with skin, except at one spot. There was no discharge. Professor Lorrain Smith's report was that there were widely dilated lymphatics and lymph spaces in a matrix of vascular fibrous tissue. The larger spaces were lined with endothelium. In the second case there was marked displacement of the eyeball forwards, which had been noticed a few weeks. There was no sign of inflammation. The pupil only reacted consensually with that of the other eye. There was marked optic neuritis in the affected eye. There were no hæmorrhages. Dr. Griffith operated 11 days after seeing the patient and removed the entire contents of the orbit in one mass, the eyelids being first reflected towards the nose by means of a horseshoe incision, the flap being afterwards replaced and sutured. The tumour consisted of small round cells, the tissue was richly supplied with thin-walled blood-vessels, and there were many widely dilated lymph spaces. Especially around the lymph spaces the nuclei were massed together, and they varied in size and chromatic contents. The third case had had protrusion of the left eye for some years, and latterly it had increased. The eye movements were good. There was recent optic neuritis, with blurring of the edge of the disc all round. There were no hæmorrhages. Shortly before the operation the vision had fallen to 6/12, and there was well-marked proptosis. No growth could be felt. The external rectus tendon and outer canthus were freely divided, and then the growth could easily be felt, obviously surrounding the optic nerve. The entire orbital contents were removed. The growth consisted of cylindrical masses made up of large epithelium-like cells, with a round central nucleus. Dr. Griffith strongly recommended the procedure he adopted in these cases. It was better to remove the lids entirely by a circular incision.—The paper was discussed by the PRESIDENT, Mr. E. TREACHER COLLINS, Mr. J. B. LAWFORD, Mr. J. H. PARSONS, Mr. G. COATS, Mr. FRANK G. THOMAS, Mr. J. B. WHARTON, Mr. J. JAMESON EVANS, Mr. R. W. DOYNE, Mr. M. S. MAYOU, Mr. S. JOHNSON TAYLOR, Mr. H. B GRIMSDALE, Dr. T. HARRISON BUTLER, and Dr. GRIFFITH replied.

Mr. JOHNSON TAYLOR read a paper on a Morgagnian Cataract. The patient was an elderly spinster who had had the condition in the left eye 25 years, without any discoverable adequate cause. The eye, doubtless from long disuse, had become amblyopic, and, though the direct pupillary light reflex was quite brisk and the tension normal, the projection was very defective. During the operation, which was a difficult one, owing to the sunken state of the eye, the small size of the cornea, and the narrowness of the palpebral aperture, no trace of a nucleus was discovered, the whole lens was found transformed into a milky fluid with the exception of some inspissated material lining the capsule, which was removed by repeated introduction of iris forceps; after a subsequent needling the vision was 5/12 (most) and J 1. Two points were insisted upon: (*a*) That operation should not be refused just because the projection was bad, if the direct pupillary light reflex was brisk and the tension normal, especially in a long-standing case; (*b*) that prevention was better than cure, and that, as a general rule, one-eyed cataracts should be operated on before getting over-ripe

(except in persons of advanced age and those the subjects of serious disease), although the other lens was perfectly clear; the advantages of such procedure must counterbalance the disadvantages and possible risks.

Mr. FRANK THOMAS and Mr. GEORGE COATS communicated a paper on a Peculiar Form of Granuloma of the Retina. The patient, a lad of 18 years, became ill in March, 1908, with influenza. Afterwards he developed pain in the hypogastrium, and suffered from retention of urine and pyrexia. He had severe pain in the left brow, and became drowsy and irritable. Routine examination of the eyes showed, in the region of the left papilla, an area resembling a greatly enlarged disc, and consisting of a central flat structureless portion, of the colour of the fundus elsewhere, surrounded by a ring of swollen nerve fibres. The retinal vessels emerged from the inner edge of this ring. The right fundus was normal. Subsequently a discharge from the left ear developed, and he recovered. Nearly two years later he came to hospital again. The eye was blind and glaucomatous, the anterior chamber very shallow, and the retina detached. Enucleation was therefore performed. Pathologically an oval yellow mass, measuring 4 mm. by 2·5 mm., was found in the stalk of the detached retina close to the papilla. The growth was purely retinal, and consisted of densely crowded cells, mostly slightly elongated. There were very little stroma and no organisation within the mass, but on its vitreous surface a small quantity of old organised tissue was found. The iris stroma was atrophic, and many small new-formed vessels were present on its anterior surface. The corneo-iridic angle was occluded. Looking to the histological characters alone the growth resembled a sarcoma more than a granuloma, but this diagnosis seemed improbable in view of its small size and slight amount of growth in two years. Moreover, primary sarcoma of the retina was unknown. An inflammatory origin was therefore probable, perhaps associated with the illness from which he had suffered — an illness accompanied by fever and a septic focus in the ear. On the other hand, had there been a septic metastasis in the retina one would have expected, after two years, a fully organised cicatricial mass, not a richly cellular tissue; moreover, there seemed to be evidence of slow progression during these two years. The histological characters did not accord well with an origin by retinal or sub-retinal hæmorrhage.

Mr. GRIMSDALE showed a case of Crystalline Opacities in the Cornea; two patients in the same family.

Mr. W. H. BRAILEY exhibited a Fixation Speculum.

Mr. F. A. JULER brought forward microscopical sections of a Neoplasm involving the Iris, from a case shown on Nov. 10th last.

Mr. CHARLES WRAY showed a Sarcoma-like Growth in the Anterior Chamber with a 16 years' history.—Mr. LAWFORD, discussing Mr. Wray's case, said there seemed to have been something visible in the anterior chamber for 15 or 16 years, but the patient said that it had increased considerably during the last two years. He thought the most likely diagnosis was that there had been a mole or innocent tumour of the iris, which had now become sarcomatous. If it were sarcoma there could be only one line of treatment—namely, removal. He would be inclined to attempt to remove the growth, and a piece of iris with it, and to examine with the microscope, basing the subsequent procedure on what the microscope revealed. He did not counsel leaving it alone.

Mr. ELMORE W. BREWERTON showed a case of Cirsoid Aneurysm.

Mr. H. L. EASON exhibited a case of Relapsing Marginal Keratitis.

## HARVEIAN SOCIETY OF LONDON.

*Discussion on Colitis.*

A MEETING of this society was held on March 9th, Mr. J ERNEST LANE, the President, being in the chair.

Dr. SIDNEY PHILLIPS, in opening a discussion on Colitis, said that so-called membranous colitis included inflammatory or true colitis and non-inflammatory cases incorrectly called colitis; he thought the latter was frequently due to spasm of the intestine. The Plombières treatment was sometimes useful. He thought that simple colitis was sometimes an early stage of ulcerative colitis, and that there was no precise distinction between them; sometimes the whole of the colon was denuded of mucous membrane. Perforation sometimes occurred, and occasionally death was deferred for days after this accident. Among symptoms were acute paroxysms of abdominal pain and also leucocytosis; neither of these occurred in typhoid fever. Hiccough was a common symptom. Prognosis was doubtful; where mucous colitis was excluded the mortality was high. As to etiology, he did not think that lead poisoning was a cause, but was convinced that acute colitis might result from articles of food or from water, and quoted cases. He thought that asylum dysentery was true dysentery, but in London colitis rarely gave bacteriological evidence of identity with amœbic dysentery. As to treatment, drugs were of little use, though calomel and opium were of value. The worst cases might recover, and appendicostomy was sometimes useful. Vaccine treatment was of use, but in very acute cases the prospects of success were small.

Mr. D'ARCY POWER said that chronic colitis might be due to simple irritation, protozoal infection, or bacterial infection, and that two classes were recognisable: (1) in which the cause could be found; and (2) in which there was a toxæmia from ulceration of unknown cause. Thorough examination was required for diagnosis, the bowel being washed out and examination made by the finger and the sigmoidoscope. Gross causes thus recognised were: (1) scybala in sacculi of the intestine; (2) polypi or cancer; and (3) certain bacterial infections. Ulcerative colitis, however, occurred apart from these causes, the lesions being chronic, destructive and extensive, and producing toxæmia. He described a case of a man who suffered from chronic constipation which became worse, and blood appeared in the stools; fissures and ulcers appeared about the anus, and the patient lost appetite and vigour. The pulse became rapid and the temperature high and irregular; the mouth was septic and he suffered from swelling of various joints. Blood and mucus persisted in the motions, which were very irregular, sometimes being passed at short intervals. After simple treatment for a long period, appendicostomy was performed and the bowel washed out daily through the appendix, with local improvement, though the patient remained very ill. A vaccine prepared from the pus was employed. The patient continued to improve, but convalescence was extremely slow, and slight relapses were frequent. The diagnosis of this condition was easy in late stages, but in early stages it gave little indication of the severity of the disease, as the patients did not look as ill as they were. Mild remedies should only be employed for a short time, after which recourse should be had to vaccine therapy and if necessary to surgery. Appendicostomy did not cure the condition, but helped to keep the bowel clean and prevent absorption of toxic products. It led to material improvement in the condition even in advanced cases, though relapses—generally temporary—might occur. For irrigation, many drugs caused irritation; he preferred carbonate of bismuth, permanganate of potassium or allmatein, and in later stages perchloride of mercury, zinc sulphate, or nitrate of silver; chlorodyne was a valuable anodyne.

Dr. W. HALE WHITE said he thought the main cause for membranous colitis was constipation. Ulcerative colitis might be secondary to disease of the appendix. Pain was an important aid to diagnosis. Acute membranous or ulcerative colitis might occur in Bright's disease. Shiga's bacillus was rarely found, but the B. coli was very frequent. The distinction between primary and secondary colitis was important. It might be secondary to infective disease, irritation, injury, or malignant disease. Primary colitis was of better prognosis. The bowel should be kept clean and empty. In mild cases castor oil should be used with rectal irrigation with plain water if necessary; failing this appendicostomy should be performed. The operation was rarely necessary in membranous, but usually so in ulcerative, colitis. Vaccine therapy was a useful addition.

Dr. JOHN MATTHEWS said that he was usually called upon to identify the organism involved in colitis and not to make a clinical diagnosis. Sometimes he had obtained organisms direct from the ulcers through a speculum which were pure B. pyocyaneus. Inoculation with this organism led to rapid improvement. Another case met with similar success with Friedländer's bacillus. As a rule he made a thin emulsion with the fæces and planted this upon neutral-red lactose-agar

plates from which discrete colonies of different organisms could be isolated. Diagnosis was made by estimation of the patient's opsonic index to the various organisms. He maintained strongly that infecting organisms do not appear in the urine, and he found that catheter specimens in these cases were almost invariably sterile. As a rule he used vaccines of coliform bacilli and occasionally a streptococcus vaccine. He gave statistics of the organisms which he had found in such cases and of his results. Out of 16 cases under his own charge he had had 10 complete recoveries.

Dr. C. W. BUCKLEY regarded mucous colitis as a catarrh of the mucous membrane due to retained fæces or bacterial toxins, and thought that associated neurasthenia or arthritis was due to the same cause. He described the Plombières treatment and he ascribed its effects to removal of toxins. He discussed the value of the fluids used at various spas and emphasised the importance of selecting a spa according to the requirements of the patient, and the necessity for skilled attendance.

Mr. L. A. BIDWELL said that colitis should generally be treated by medical methods and that surgical treatment was comparatively rarely needed, but he wished to speak on operative methods. He agreed that colitis sometimes depended on appendicitis and found that the removal of a diseased appendix often led to cure, but not always. If the appendix were healthy appendicostomy should be performed, but if diseased it should be removed. A form of colitis with single deep ulcers producing adhesions was a distinct type. In these perforation often followed, and since they showed a tendency to recur he advocated ileo-sigmoidostomy. This operation was only to be performed when the lower half of the sigmoid was healthy as determined by the sigmoidoscope. The ileum should be divided between the anastomosis and the cæcum. Troublesome diarrhœa did not follow the operation.

Dr. W. H. WILLCOX also spoke.

## LIVERPOOL MEDICAL INSTITUTION.

*Exhibition of Specimens.—Sleeping Sickness.*

A MEETING of this society was held on March 2nd, Dr. T. R. BRADSHAW, the President, being in the chair.

Mr. W. THELWALL THOMAS and Dr. STOPFORD TAYLOR showed: 1. A large Intracanicular Fibroma of the Breast (weight 7 lb.) containing cyst removed from a patient, aged 44 years; the fibrous tissue was undergoing myxomatous degeneration and in one place had fungated through the skin. 2. A large round and oval-celled Periosteal Sarcoma of the Scapula of a female, aged 20 years; an interscapulo-thoracic amputation was performed. 3. A large Cancellous Exostosis from the lesser trochanter of the femur in a patient who had 14 others, small in size, distributed at the epiphyseal ends of many of the long bones.

Mr. D. DOUGLAS CRAWFORD showed: 1. A Right Kidney with large branching calculus removed from a woman, aged 65 years, producing no symptoms except occasional pus in the urine. 2. Volvulus of the Lower End of the Small Intestine, which had lodged in the pelvis, producing symptoms of appendicitis in a woman, aged 31 years; it was excised with excellent result. 3. With Dr. MOORE ALEXANDER: Embryoma, probably Malignant Degeneration of the remains of Branchial Cleft, from a man, aged 21 years, which had grown rapidly recently. Cysts were present. Microscopically there were carcinomatous masses and tubes lined by ciliated epithelium.

Dr. K. W. MONSARRAT showed a Sacral Dermoid.

Dr. ERNEST E. GLYNN showed: 1. A specimen of Cellulitis and Suppurative Thrombosis of the Orbit due to Actinomyces; pus was found in the sella turcica. The source of infection was not discovered. 2. Multilobular Cirrhosis of the Liver, with multiple, small, old and recent red thrombi in the capillaries and smaller branches of the hepatic and portal veins. The cause of the thrombosis was not discovered. 3. Enormous Dilatation of the Bladder without Obstruction from Urethral Stricture or Enlarged Prostate; the dilatation was proved microscopically to result from chronic interstitial myositis following chronic cystitis.

Dr. R. J. M. BUCHANAN demonstrated a Method for the Examination of Red Blood Corpuscles by means of Edington's solution in combination with stains. The blood was mixed in a Thoma-Zeiss pipette, with a solution, then placed on a slide and allowed to dry. The erythrocytes by this method did not undergo any distortion from spreading.

Dr. BUCHANAN read a note on the appearance of the Erythrocytes from a case of Recurrent Attacks resembling Henoch's Purpura for 13 years. When examined by the method just described 90 per cent. of the erythrocytes from the peripheral circulation contained one or more peculiar basic staining bodies not unlike parasites. The blood in the urine contained identical bodies.

Dr. J. O. WAKELIN BARRATT exhibited the Technique of making Models of Cells undergoing Mitosis. This demonstration was illustrated by models, sections under the microscope from which the models were constructed, and by lantern slides. Reference was also made to the bearing which the forms of mitoses exhibited had upon pathological processes, particularly upon cancer and proliferating surface epithelium.

Dr. J. W. W. STEPHENS read a paper on Recent Researches in Sleeping Sickness, dealing with the following points: 1. Were there other species than trypanosoma gambiense which caused sleeping sickness in man? He pointed out that some of the trypanosomes had a nucleus at the posterior end. This trypanosome was also far more pathogenic for animals than T. gambiense. It remained to be seen whether this trypanosome was really different from gambiense. 2. The mode of transmission of T. gambiense. Up to recently it was believed that the transmission was mechanical, but recent work had shown that the fly was not infective until 20 or 30 days after biting an infected person. 3. What was the reservoir of sleeping sickness? Probably antelope and cattle and some of the domestic animals must be regarded as potential reservoirs. 4. Was sleeping sickness curable? In the early stages it was practically certain that some cases had been definitely cured by arsenic or antimony used in various ways, but if the trypanosome gained access to the subarachnoid space it was doubtful whether a cure was possible.—Dr. K. A. GROSSMANN asked whether any explanation could be given of the increased virulence of sleeping sickness in Africa?—Dr. STEPHENS, in reply, stated that sleeping sickness had been known for about 100 years, and that where a virgin population existed the disease spread with terrible rapidity, but that in other areas where the disease was still endemic it appeared not to spread. The explanation of the difference was not clear.

*Exhibition of Cases —A Rare Arthropathy.—Septic Puerperal Thrombo-phlebitis of the Pelvic Veins.*

A MEETING of this society was held on March 9th, Dr. T. R. BRADSHAW, the President, being in the chair.

Mr. C. THURSTAN HOLLAND showed a series of lantern slides illustrating the Modern Short Exposure in X Ray Work: kidney stones taken with an ordinary coil and mercury break with exposure of less than one second; chests and stomachs taken with the Snook apparatus in a fraction of a second exposure; chests taken with the single flash 1/100th second Dessauer apparatus. It was interesting to note that the first successful radiograph taken in Liverpool in January, 1896, by Sir Oliver Lodge, was a hand with a bullet in it and that the exposure was one and three quarter hours.

Mr. C. G. LEE showed an infant aged 4 months. The patient had a Coloboma of the Iris in the Right Eye and a Left Microphthalmic Eye, placed far back in the orbit, with a large cystic swelling extending into the tissues of the lower lid. The skin of the lower lid was much stretched and of a bluish colour and semi-translucent. Mr. Lee said that whilst coloboma of the iris was, perhaps, the most common ocular developmental defect, microphthalmia was, with cystic extension, one of the rarer forms of this affection.

Dr. C. J. MACALISTER read a note on a Rare Arthropathy, and showed photographs of two patients suffering from it. The one case was a woman advanced in life, the other being a child aged 6 years. The characteristic features in each were that the knees were dislocated, both the ankles were ankylosed, and there were partial dislocations of both wrists, of the elbows, and shoulders; the neck was bent forward and fixed in the case of the woman; the small joints of the hands and feet were similarly affected. The disease in each case began somewhat acutely with fever and swelling of the affected joints. The initial attack was followed after periods of remission by other exacerbations, and the dislocation of the joints took place in each case rather suddenly.

The change was in its nature an osteo-arthritis, with rarefaction of the bony ends and disappearance of the cartilages. In the case of the child there was a condition of the skin resembling a scleroderma, and the skin over each knee resembled a thin cicatrix.—Dr. W. B. WARRINGTON pointed out that a sclerosing process affected in the more usual cases the skin only, as in the diffuse form of scleroderma, but that sometimes the muscles were also affected and in rare cases the bones as well. He alluded to an instance of the latter condition which had also been seen by Dr. Macalister, Mr. Robert Jones, and Dr. F. H. Barendt.

Dr. W. BLAIR BELL read a paper on Septic Puerperal Thrombo-phlebitis of the Pelvic Veins. In the first place the pathology of the condition was discussed, next the frequency of occurrence and prognosis. It was pointed out that according to the figures of Lenhartz, Trendelenburg, and others septic thrombo-phlebitis was the only gross lesion found in one-half of the cases that died from puerperal sepsis; in other words, at least one woman in every thousand delivered died from this condition. The question of operation was based upon the principle accepted in tying the internal jugular vein in septic infection of the ear to prevent general pyæmia. At present the mortality of the operation was extremely high because it had nearly always been resorted to as a last expedient. With earlier operation the mortality would be reduced. The diagnosis was the chief difficulty. The following points should be considered: (1) The late onset—10 to 20 days after parturition and following a moderate degree of morbidity; (2) rapid rise in temperature and pulse-rate generally with rigors; (3) mobility of the uterus; (4) absence of pain; and (5) dark colouration of the cervix from venous congestion. Two cases upon which Dr. Blair Bell had operated were described: the first, an unsuccessful one, had already been recorded in full, the second had recently been the subject of the operation and was now quite well. Dr. Blair Bell pointed out that the operation was a great scientific advance on the expectant treatment, which had resulted in a general mortality for all cases of at least 65 per cent. With early diagnosis and operation the mortality should be reduced to about 5 per cent.—Dr. ERNEST E. GLYNN considered that general pathological considerations justified the operation.—Dr. ARTHUR J. WALLACE spoke in favourable though guarded terms of the procedure, whilst Professor H. BRIGGS held that familiarity with figures and statements concerning the past—peripatetic—methods of treatment in cases of puerperal fever brought out the fundamental difficulty in separating the local from the general infections. He himself was a firm advocate of early local treatment, but believed that on the evidence now available the term septic thrombo-phlebitis was misleading from confusion between the changes in the thrombi themselves and in the surrounding tissues.

## LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

*Inhibition of Growth of Inoculable Tumours in Rats.—The Human Pituitary Gland.—Nutrient Media for Naked-eye Recognition of B. Diphtheriæ.—Exhibition of Specimens.*

A MEETING of this society was held on March 3rd, Dr. J. B. HELLIER being in the chair.

Dr. A. S. F. GRÜNBAUM and Dr. H. G. GRÜNBAUM made a communication on Inhibition of Growth of Inoculable Tumours in Rats, showing, among other things, that antivenom serum caused almost invariably regression of growths which were within a certain size limit at the time of its injection. An apparent antagonism between tumour growth and immunisation to cobra venom was also described.

Dr. A. S. F. GRÜNBAUM and Dr. H. G. GRÜNBAUM gave an account of the Human Pituitary Gland based on the examination of over 50 specimens. They showed that the colloid material did enter the blood vessels, and drew attention to the frequent occurrence of multinuclear areas in cases of malignant disease.

Dr. MYER COPLANS showed specimens of new Culture Media as a means for the readier recognition of B. diphtheriæ in subcultures from swabs of suspicious nose and throat cases. The media were made as follows: To sheep's blood serum to which there had already been added 1 per cent. glucose—acid producer—and 1 per cent. of ½ per cent. aqueous solution of neutral-red—indicator—(this preliminary combination being denoted as "S")—there were added, either singly or in combination, one or more of the following salts: (*a*) potassium sulphocyanate, 1 per cent.; (*b*) potassium ferrocyanide, 2½ per cent.; (*c*) potassium ferricyanide, 1 per cent.; (*d*) boric acid, about 1 per cent. The medium on coagulation and inspissation should be faint primrose-yellow in colour, the reaction being faintly alkaline. The sheep-serum was best pipetted off from recently drawn clotted blood and then allowed to stand in a refrigerator for three days in order to eliminate red corpuscles by sedimentation, only the supernatant liquid being finally utilised. With combination S. (*a*) B. diphtheriæ grew red with a bluish-pink tint diffusing through the medium in all directions; B. Hoffmann grew yellow with yellowish diffusion; some varieties of staphylococci simulated B. diphtheriæ on culture but on further incubation the tint did not intensify as with B. diphtheriæ and should be readily distinguished; B. subtilis grew brownish; B. megatherium and torulæ grew as faint pinkish-white colonies which were raised; streptococci grew apparently colourless. Combinations S. (*a*) (*b*), S. (*b*), and S. (*d*) in particular showed up to advantage the reddening and bluish-pink diffusion brought about by B. diphtheriæ as compared with various staphylococci. Confirmation as to the diagnostic value of the combination S. (*a*) had been furnished by Dr. C. Rankin, senior assistant medical officer to the Leeds City Fever Hospitals, who had used the medium in more than a thousand cases as a test for the absence of B. diphtheriæ from the nose and throat in patients already convalescent from the disease as a preliminary to their discharge from hospital. Suitable control measures had been carried out all along, and as a result of this experience it was possible to adopt the dictum, "no red colouration, no B. diphtheriæ," seeing that there had not as yet been a single exception to the rule. The test was by means of the naked eye and the labour of microscopic examination was greatly reduced since it was possible after a short experience to distinguish readily, at a distance, the various tints produced, either from the front or back of the changed medium. In case of doubt further incubation intensified the tints and facilitated the naked-eye diagnosis. These results were part of a research to determine the effect of salts of saliva on the growth of the mouth and intestinal organisms in nutrient media.

Dr. COPLANS further showed slides—(1) Splenic Puncture (Kala-Azar); (2) Splenic Puncture, Kala-Azar Infantum (Infective Splenic Fever in Children, Mediterranean); and (3) Brain Section and Blood from a case of Malarial Coma.

Dr. HELLIER showed: 1. A Fœtus stillborn in the seventh month, showing complete absence of bladder, ureters, and kidneys. A well-formed uterus with normal appendages was present. The hands and feet were webbed. 2. An Intramural Abdominal Myoma removed from the Abdominal Wall during Pregnancy. The myoma had grown with great rapidity and showed some signs of necrobiosis. There were no ill effects from the operation.

Mr. H. LITTLEWOOD and Dr. M. J. STEWART showed specimen and section from a case of Adeno-carcinoma of the Sigmoid Flexure associated with Tuberculous Disease of the Right Fallopian Tube.

Mr. B. G. A. MOYNIHAN and Dr. STEWART showed the Viscera from a patient in whom complete gastrectomy for carcinoma was performed an May 31st, 1907. Death occurred on Feb. 1st, 1911, being preceded by grave anæmia for some months, between the onset of which and the operation the patient had remained well.

Dr. STEWART showed a specimen from a case of Epithelioma of the Pharynx; death occurred from impaction of a large piece of meat.

## DEVON AND EXETER MEDICO-CHIRURGICAL SOCIETY.

*Sudden Serious Peritoneal Lesions.*

A MEETING of this society was held on March 3rd, Mr. J. M. ACKLAND, the President, being in the chair.

Dr. WILLIAM GORDON read a paper on the Diagnosis of Sudden Serious Peritoneal Lesions. He divided the conditions simulating sudden serious peritoneal lesions into: (1) intrathoracic diseases (pneumonia, pleurisy, pericarditis); (2) the four colics (hepatic, renal, pancreatic, intestinal); (3) nervous cases (locomotor ataxy, hysteria);

(4) acute irritant poisoning; (5) cholera and typhoid; (6) uræmia; (7) mucous colitis; (8) acute gastric dilatation; and (9) acute intestinal obstruction by gall-stones. He classified the "sudden serious" peritoneal lesions as follows: 1. Ruptured ectopic gestation. 2. Acute intestinal obstructions: intussusception, strangulation by bands, volvulus, internal hernia, strangulation through apertures. 3. Perforations of the alimentary canal: gastric ulcer or cancer, duodenal, typhoid, tubercular, appendical, of the colon. 4. Rupture of other structures except abscesses: gall-bladder, common bile-duct, ovarian cyst, bladder, hydatid cyst. 5. Rupture of abscesses: appendical, pyosalpinx, lymph gland abscess, acute phlegmonous cholecystitis, liver abscess, empyema, renal abscess, pericardial abscess, subdiaphragmatic abscess, suppurating ovarian cyst. 6. Acute torsions (not intestinal): ovarian cyst, subperitoneal fibroid, dilated Fallopian tube, wandering spleen, floating kidney, undescended testis, omentum. 7. Acute pancreatitis and pancreatic hæmorrhage. 8. Acute peritonitis not due to the foregoing (tuberculous, gonococcal, pneumococcal). 9. Sudden vascular lesions: rupture of aneurysms, portal thrombosis, embolism of superior mesenteric artery. Dr. Gordon considered the term "abdominal catastrophe" as one embracing at the same time too much and too little. Peritonism, again, was a term purely symptomatological, and not wholly satisfactory at that, whilst the expression "acute abdomen" was obviously only an ingenious makeshift. He ventured to submit that in practically all the conditions recalled, when they spoke of abdominal catastrophes, the common factor which determined the clinical course was the peritoneal lesion. He further suggested that this lesion was characterised by symptoms of sudden onset, and by consequences too grave to associate with merely trifling injuries. He hoped therefore that by a grouping together of these lesions their knowledge of them might become more precise, and some advance be made in the matter of diagnosis. In considering the intrathoracic diseases which might simulate peritoneal lesions Dr. Gordon drew special attention to pericarditis and the motionless abdomen in respiration which might accompany it. He also mentioned as a valuable sign the absence of, or at all events reduction in, the plantar and pharyngeal reflexes in hysterical cases. Here also a leucocyte count would be of value. The difficulties met with in the diagnosis of acute dilatation of the stomach simulating obstruction and of obstruction by gall-stone were referred to at some length. Turning to the lesions which formed the main subject of his paper Dr. Gordon said that he merely intended rapidly to review them and to suggest points for discussion. The administration of opium would obscure almost all the diagnostic features on which he was about to lay stress. He considered that ruptured ectopic gestation was more often missed from oversight than from ignorance, and urged the marked and increasing pallor as a prominent sign. Fortunately, conditions with which it might be confounded called for the same treatment. In acute intestinal obstruction Dr. Gordon raised the question as to whether the period of repose, so often seen in perforative cases, was not absent. He found himself in a vast field when confronted with the perforations and felt obliged to limit himself to a few points. He was of opinion that upward extension of gastric resonance was more important than loss of liver dulness in the mammary line, often late in its appearance and often misleading. He put as a question to the surgeons present whether, as a point of contrast, shock did not develop rapidly after a perforation, whereas in strangulation the condition was of gradual onset. Dealing with rupture of abscesses and their diagnosis Dr. Gordon mentioned the ease with which most of these conditions could be confused with appendicitis; for example, ruptured pyosalpinx or phlegmonous cholecystitis. Pancreatic lesions might often simulate obstruction, but points to be noted were absence of fæcal vomiting and an epigastric swelling. Jaundice with no sign of hepatic disease would be suggestive. The stools should be carefully observed. Where doubt existed as to the diagnosis between gall-bladder or pancreatic tumour Dr. Gordon suggested the knee-elbow position, when a gall-bladder would come to the palpating hand and a pancreatic recede from it. Vascular lesions could rarely be diagnosed except by operation. Dr. Gordon finally asked for the opinion of the society as to (1) whether diagnosis would not be intensified by a closer study of abdominal pain in all its aspects; (2) importance of time of onset of collapse in diagnosis; (3) blood examinations as an aid to diagnosis; (4) the value of more frequent examinations under anæsthetics; and (5) how far a study of the vomited matter helped them in distinguishing lesions.

Mr. F. W. LANGRIDGE described what he considered to be the mechanism concerned in abdominal movements, and alluded to the viscero-motor reflex. It did not follow that abolition of this reflex meant acute peritonitis.

Dr. R. V. SOLLY did not consider that the taking of one blood film was of much help to a diagnosis. Unless a series were examined the results might be most misleading.

Mr. R. PICHARD quoted a case on which he had operated and where the signs of perforation were practically absent. He brought forward this case as an example of an undisturbed temperature, pulse, respiration ratio in perforation, and as going to prove that the negative aspect of symptoms was far less reliable than the positive.

Dr. J. RAGLAN THOMAS recalled a case resembling in all outward particulars a ruptured ectopic gestation, but which at operation proved to be rupture of a pelvic abscess.

Mr. ADAMSON remarked on the frequency with which relatively unimportant symptoms prior to the onset of an acute lesion mislead one. He instanced the case of a girl who had been under his care for symptoms suggestive of gastric ulcer, and to whom he was urgently summoned. Taken with her previous history her condition suggested acute perforation, but on opening the abdomen that cavity was found to be full of blood originating from the rupture of a broad ligament vessel. Mr. Adamson also held as equally misleading the variability of pain and the difficulty which lay in its interpretation.

Dr. GORDON replied.

## EDINBURGH OBSTETRICAL SOCIETY.

*Toxæmia of Pregnancy.—Gastro-mesenteric Ileus as Post-operative Complication in Abdominal Cases.—Double Tuberculous Pyosalpinx.*

A MEETING of this society was held on March 8th, Dr. F. W. N. HAULTAIN, the President, being in the chair.

Dr. R. W. JOHNSTONE read notes on Some Experiments on the Anaphylactic Theory of the Toxæmia of Pregnancy. After describing the condition of anaphylaxis and instancing some of its manifestations, he referred to the fact that Anderson and Rosenau in 1908 first suggested a possible connexion between anaphylaxis and the toxæmia of pregnancy. The points of resemblance were chiefly the occurrence of convulsions during life, and after death the presence of multiple hæmorrhages throughout the body. The theory was that some alien protein might pass from the placenta to the mother and supersensitise her, and that a second transference of the same substance after a suitable interval might account for the onset of convulsions and other symptoms. Anderson and Rosenau obtained anaphylactic symptoms in a guinea-pig by using an extract of guinea-pig's placenta, which, however, was allowed to autolyse before use. Dr. Johnstone in his experiments used extracts of fresh human placenta and also extracts of guinea-pig and rabbit placentæ. He obtained no positive results with eclamptic human placenta. No results followed the use in pregnant guinea-pigs or rabbits of extract or emulsion of placenta from animals of the same species. By the use of extract of normal human placenta he obtained anaphylaxis in 8 out of 12 rabbits. This he regarded as definitely due to placenta proteins. The fact, however, that he was unable to confirm the results of Anderson and Rosenau in the use of homologous placental extracts appeared to negative any connexion between anaphylaxis and the toxæmia of pregnancy.—The PRESIDENT, Dr. A. H. F. BARBOUR, Dr. J. W. BALLANTYNE, Dr. H. O. NICHOLSON, and Dr. JAMES RITCHIE discussed the paper.

Mr. E. W. SCOTT CARMICHAEL read a paper on Gastro-mesenteric Ileus as a Post-operative Complication in Abdominal Cases. He instanced three cases. He had operated on the first for suspension of a retroverted uterus. The patient began to vomit on the third day and continuously till the seventh. She was extremely ill and seemed to be suffering from delayed chloroform poisoning. The nurse turned her on to her left side and somewhat on her face, when she vomited from two to three pints of fluid, and was never sick

again, with complete recovery. Mr. Carmichael was called to see a patient, in the absence of the surgeon, who had been operated on for hydatid cyst of the liver. Sickness had begun on the day after the operation and had continued uninterruptedly for a week, when general peritonitis was suspected. She was emaciated, dyspnœic, and in great distress. The abdomen was distended, but especially in the epigastrium and left half of the abdomen as far as the hypogastrium, but though tender the abdomen was soft, and splashing could be detected. A stomach-tube was passed and five pints of straw-coloured fluid were drawn off. This gave great relief, but in a few hours the vomiting had returned and the patient was very ill. As she was very weak, and rather than expose her to the risk of her atonic stomach filling again, he decided to perform a gastrostomy under ether, removing at the same time 4½ pints of fluid. The stomach was found to be a flaccid bag completely atonic, extending into and filling the pelvis and left iliac fossa. The dilatation extended into the duodenum as far as the duodenc-jejunal flexure, the rest of the small intestine being completely collapsed. After emptying the stomach it contracted visibly up to almost its normal dimensions. The patient died suddenly five hours after operation from exhaustion. A post-mortem examination revealed the stomach and duodenum almost normal in size and no obvious cause to explain the condition. A third case had also dilatation of the stomach with splashing and succussion, with continuous vomiting for three days. The condition was immediately relieved on emptying the stomach with a stomach-tube. Two days after there was vomiting of one pint of bilious fluid without effort, and then it ceased entirely. The chief etiological factor in all these cases seemed to be some condition which produced paralysis with hypersecretion. A similar condition had been observed to complicate eclampsia and puerperal septicæmia. It was important to recognise the condition early, and it should be suspected in all cases of chloroform sickness persisting after the second day. The fluid vomited was very irritating to the lips and cheeks. If recognised early, practically all could be cured by passing the stomach-tube. As a last resort, where the condition has led to the starvation of the patient, gastrostomy, jejunostomy, or gastro-enterostomy has been performed to drain the stomach.—Dr. BARBOUR, Dr. JOHNSTONE, Dr. NICHOLSON, and the PRESIDENT made remarks on the paper.

Dr. BARBOUR and Dr. B. P. WATSON gave a demonstration of specimens of the Cystic Ovary, showing the different varieties and a lantern demonstration of the microscopical characters. The frequency with which the condition is associated with salpingitis was pointed out. This probably depended on secondary infection of the ovary from the tube, resulting in a sclerosis of the surface which prevents the rupture of the follicles. It is wrong to class these cystic ovaries among ovarian tumours, as there is no new growth, the cysts being simple retention cysts directly derived from the Graafian follicle.

Dr. BARBOUR and Dr. WATSON also described and gave a lantern demonstration on three cases of Double Tuberculous Pyosalpinx. In one the tube was so large as to reach the level of the umbilicus, filling up the whole hypogastric region. Lantern slides were shown to illustrate the pathology and mode of spread of the tuberculous process. The picture was the same in all. In the less dilated parts of the tubes there were extensive tuberculous deposits in the mucous membrane, which was greatly thickened and had the neighbouring projections fused together. In this mucous membrane there was a very marked proliferation of the epithelium, which was arranged in gland-like spaces and in solid masses, giving an appearance like carcinoma. Where the tuberculous process was advancing the epithelium was proliferating, but in the regions where many tuberculous deposits were present it was rapidly degenerating. In the more dilated parts of the tubes at the outer ends the mucous membrane was almost entirely destroyed by tuberculous ulceration, and in the very large tube a process of natural cure had occurred. At the undilated uterine ends the mucosa was healthy, but tubercle nodules were present in the muscle wall. From a study of the specimens Dr. BARBOUR and Dr. WATSON conclude that the infection is probably a direct one of the mucous membrane through the fimbriated end from the peritoneal cavity.—The PRESIDENT, Mr. SCOTT CARMICHAEL, and Dr. JAMES YOUNG commented on the paper.

# ROYAL ACADEMY OF MEDICINE IN IRELAND.

## SECTION OF SURGERY.

*Appendicular Dyspepsia and Treatment of Diffuse Peritonitis. —Appendicectomy.*

A MEETING of this section was held on March 3rd, Mr. R. H. WOODS, the President, being in the chair.

Mr. R. CHARLES B. MAUNSELL, in a paper on Appendicular Dyspepsia and on the Treatment of Diffuse Peritonitis, pointed out that the title appendicular dyspepsia was applied to a group of symptoms which had not had public attention drawn to it until Mr. Moynihan published his paper on the subject last year. Mr. Maunsell read the histories of a few examples, and stated that, in his opinion, there were two forms of the grouping of symptoms. In the first form the symptoms were mainly gastric, in the second mainly intestinal. A warning note was sounded with regard to other possible abdominal causes of reflex gastric disturbance, and special attention was drawn to the fact that the demonstration of chronic appendicular disease did not eliminate the possible presence of organic gastric disease. The concluding portion of Mr. Maunsell's paper consisted of a strong condemnation of flushing with saline solution in cases of peritonitis following perforation of the appendix, and advocating removal of the appendix and the insertion of "cigarette" drains into the pelvis and kidney pouches, which method of treatment Mr. Maunsell and others had found uniformly successful even in most advanced and apparently hopeless cases of peritonitis.

Dr. W. S. HAUGHTON read a paper on Appendicectomy, with Special Reference to the Treatment of Adhesions. He recommended that in all cases of operation on the appendix during the "cold" stage a search should be made for adhesions, the result of previous attacks of acute inflammation. There would be found in many cases kinks in the intestine due to bands which should be divided. He had found in all cases in which he examined for it a thin membrane spread over the cæcum and ascending colon, rendered visible only by the fine network of blood-vessels which ramify in it. The division of this always caused the cæcum to bulge forward, showing that it had previously been bound down by this membrane. He advocated crushing the base of the appendix before removing it. The crushed part should be then cut through and invaginated beneath a purse-string suture.

Mr. MAUNSELL said he would be inclined to crush the stump close to the clamp, ligature with silk and top sew. The method advocated by Dr. Haughton, he said, sometimes led to hæmorrhage from the bowels.

Dr. H. STOKES mentioned a case of appendicular dyspepsia with symptoms suggesting duodenal ulcer. Subsequently pain was referable to the appendix, which was removed. It was very diseased, while the duodenum seemed normal, but the dyspepsia remained. He thought adhesions in the chronic stage should be divided.

Dr. W. G. HARVEY said with regard to acute fulminating appendicitis that there were usually many abscesses, and unless the appendix was removed and all infected cavities were drained, the patient went from bad to worse. With regard to appendicular dyspepsia, he thought somewhat similar symptoms might occur in floating kidney, gall-stones, or pelvic trouble. Where the appendix lay behind the cæcum the symptoms produced simulated those of acute biliary obstruction.

Mr. R. A. STONEY said there was a condition which explained the recurrence of pain when the appendix was removed, and that was the dilatation and abnormal mobility of the cæcum. There was a stasis of abnormal contents in the cæcum. The opening from the appendix into the cæcum was dilated, which resulted in the passage of the intestinal contents into the appendix, and a chronic appendicitis was set up. These cases were supposed to be due to adhesions. When a ligature was applied to the stump of the appendix there was danger of locking up a certain amount of sepsis between the ligature and the purse-string suture. Pus might form and burst into the peritoneal cavity. He always ligatured the appendix with catgut instead of silk, and used silk for the purse-string suture. A distinct hæmorrhage might occur from the vessels of the appendix where

it was crushed and not ligatured, which hæmorrhage escaped into the cæcum.

Mr. L. G. GUNN, Mr. A. J. BLAYNEY, and Sir C. BALL also spoke.

OXFORD MEDICAL SOCIETY.—A meeting of this society was held on March 10th, Mr. R. H. Anglin Whitelocke, the President, being in the chair.—Dr. W. A. P. Waters showed a case of Mitral Stenosis in a young man, aged 21 years, who had twice had chorea at an early age. Subjective heart symptoms were first noticed at 14 years. The heart was very large, with a marked retraction at the apex. The remarkable feature was an antero-posterior curvature of the spine, which had been becoming much more marked lately. The case was shown in order to elicit opinions whether the spinal and heart conditions were in any way related.—Dr. E. Mallam mentioned a patient with lateral curvature of the spine in whom he had watched the development of mitral stenosis. —Dr. A. G. Gibson mentioned the views of certain French writers that there existed a close relation between thoracic deformity and enlargement of the heart.—Mr. A. P. Dodds-Parker showed a case of Tertiary Syphilis which he had recently treated by the intravenous injection of salvarsan. The patient had been previously treated with mercury and potassium iodide with very partial success, but since the injection (three weeks previously) the lesions of the frontal bone had completely healed and a subcutaneous gumma near the angle of the jaw had aborted. The patient had had no inconvenience from the injection.—Mr. Dodds-Parker described the details of the intravenous and intramuscular methods of injection and demonstrated the apparatus.—Mr. E. C. Foster read the history of a case of Pyelitis following Pregnancy in a woman aged 30 years, the onset appearing two months after the birth of the child. She recovered but had several other attacks, three occurring two days before the onset of menstruation. Mr. Foster thought them due to retained products following pregnancy. Curetting was not done as the patient made fairly rapid recoveries, and was now in good health.—Mr. H. E. Counsell related the case of a postman, aged 22 years, who had laryngitis and sore-throat. Nothing more than an ordinary cold was suspected, and the patient improved a little on staying indoors. Six days later he had great difficulty in breathing and appeared moribund. He recovered, but the same day had another attack and died. There had been no laryngeal obstruction necessitating tracheotomy. A culture of the throat showed the presence of streptococcus. Subsequent questioning of his landlady showed that the patient had suffered recently from what appeared to be peripheral neuritis in the legs, that he had been in the habit of drinking enormous quantities of fluid, and that he had passed large quantities of urine. Mr. Counsell believed that this case was undoubtedly one of diabetic coma.—Dr. H. T. Gillett related the history of a middle-aged woman who was suddenly attacked with hæmorrhage from the bowel necessitating surgical interference. The greater part of the transverse colon was found to be much thickened and dark red in colour. The transverse meso-colon showed petechial hæmorrhages. As the patient had mitral regurgitation, the intestinal condition was thought to be due to infarct, and a short circuit was performed, but the patient did not recover. On post-mortem examination no evidence of infarct was found. The localisation of the affection to the middle part of the transverse colon was very definite. The mucous membrane and sub-mucous layer of the intestine were necrotic and showed the invasion of organisms from the lumen of the bowel. The muscular layer and peritoneum were in a state of acute inflammation.—Dr. M. C. Hayward related a case of Saccular Aneurysm of the Second Part of the Aorta in a man aged 58 years. The patient had persevered for six weeks in a rigid Tufnell treatment, which was effective in relieving all symptoms, but had left some wasting of the upper arm muscles; these had subsequently recovered their power. Later the patient developed an epithelioma of the palate, for which he was successfully operated upon, and was now in good health.

UNITED SERVICES MEDICAL SOCIETY.—A meeting of this society was held on March 8th at the Royal Army Medical College, Colonel Sir David Bruce being in the chair.—Lieutenant-Colonel P. J. Freyer, I.M.S. (retired), read a paper on the Symptoms and Diagnosis of Stone in the Kidney, Ureter, and Bladder. After detailing the various symptoms present in these conditions, he laid special stress on the value of radiographs of the parts as a precedent to operation; in his opinion it was only in exceptional cases that one would be justified in operating on a suspected case of stone in the kidney or ureter without having the diagnosis confirmed by an X-ray photograph.—Dr. W. Ironside Bruce showed a number of Radiographs from cases of Stone in the Kidney, Ureter, and Bladder. In his remarks he emphasised the necessity for always taking the picture in a standard position.—Colonel H. G. Hathaway, A.M.S., read a paper on Ambulance Transport. After pointing out that there was likely to be a shortage of horses in future campaigns on account of the large growth of motor transport, he gave as his opinion that it would be necessary to provide motor transport for wounded in all cases except at the immediate front, where it would still be necessary to have horse transport on account of the difficulties of getting motor wagons over rough country away from roads. The use of motor transport would have many advantages, not only in the more rapid clearing of the front, but also in the greater comfort to the wounded and quicker attention to their needs in the better adapted hospitals of the rear. He discussed the various types of motor vehicle at present in use, and suggested that the most economical method of use would be to remove the body and replace it by a platform adapted for the carriage of wounded lying down or sitting up. If large users of motor transport in peace-time were subsidised it might be possible to arrange that they should have their chassis built to standard sizes which in war-time would fit bodies kept in mobilisation stores.—Major Crofton Atkins, A.S.C., said that the War Office had, of course, had the matter of motor transport under serious consideration for some time. Probably the best solution of the problem would be the subsidising of cars with a standard chassis; these would be registered and would be available for military purposes in case of mobilisation. It was doubtful if motors could be much used away from roads, but on roads he thought there was no doubt that they would add greatly to the comfort of the wounded as well as facilitate their more rapid removal to the rear.

# Reviews and Notices of Books.

*Puerperal Infection.* By ARNOLD W. W. LEA, M.D., B.S. Lond., B.Sc. Manch., F.R.C.S. Eng., Lecturer in Obstetrics and Gynæcology in the University of Manchester; Surgeon, Northern Hospital for Women; Assistant Surgeon, St. Mary's Hospital, Manchester. London: Henry Frowde and Hodder and Stoughton. 1910. Pp. 384. Price 25*s.* net.

THE advances made in the last 20 years in our knowledge of the bacteriology of puerperal infection have been very considerable, but even now we are not in a position to distinguish, at any rate by bacteriological methods, between the various forms which this disease may assume. The importance of this form of infection can hardly be overestimated, since it is still responsible for nearly half the deaths of women occurring in child-bed, and it certainly accounts for a very large number of the cases coming under the care of the gynæcologist.

These facts must be considered sufficient justification for the length of this monograph, extending as it does to some 384 pages. Dr. Arnold Lea has written the book with the intention of presenting what is known of puerperal infection with some degree of scientific precision, and certainly he has attained his object. Our only criticism of the work is that there is a great deal of repetition, and the whole suggests to the reader a collection of isolated essays rather than a single work dealing with the entire subject. If more care had been taken in this respect the contents of the book could have been compressed within a smaller compass with advantage. The repetition which exists is, however, not without its advantages, for the author is enabled thereby to make certain

important statements several times over, and in this way to lay a corresponding amount of stress upon them.

After a short chapter devoted to a historical review, Dr. Lea attempts to define and classify puerperal infections. On the whole he accepts the statement of von Herff that all forms of puerperal infection are due to invasion of wounds by living organisms, and must be regarded as essentially the same whether the organisms lead to intoxication or to general invasion of the blood-stream. After reviewing the mortality and morbidity of puerperal infection, the conclusion is arrived at that the mortality of this disease has been reduced to as little as 0·1 or 0·2 per cent. in lying-in hospitals, but that outside such hospitals it has shown little diminution, while the morbidity even in other hospitals is still between 10 and 20 per cent.

In the section dealing with the bacteria of the genital canal the results of 58 cases investigated by Dr. Sidebotham and the author are given, and it is stated that in 80 per cent. of the cases pyogenic organisms were found in the early days of the puerperium in the interior of the uterus. In view of the fact that in some 90 per cent. of the cases the puerperium ran an uneventful course, it is probable that such organisms exist only in small numbers and possess but little virulence. It has been suggested by Fromme and other observers that the virulence of any streptococci that may be present can be measured to some extent by their hæmolytic power. Although the researches so far carried out show that in cases of severe infection the streptococci present as a rule possess marked hæmolytic power, yet this is by no means a constant sign, since organisms having this same property may be found in cases running a perfectly afebrile course. As Dr. Lea truly remarks, it is not possible to assert therefore that hæmolysis forms an absolute distinction between the saprophytic and slightly virulent organisms and those which are pathogenic. In connexion with the question of auto-infection, he states that, while such infection is extremely rare, yet it may occur, inasmuch as the vulva and lower portions of the vagina frequently contain pathogenic organisms which may ascend into the uterus.

There are two very good chapters dealing with the general pathology and pathological anatomy of puerperal infection in considerable detail. Dr. Lea holds, and in our opinion quite rightly, that in the early stages of puerperal infection it is often impossible to distinguish with certainty between the symptoms due to pure toxæmia and those due to septicæmia, as in both forms of infection they are essentially due to the bacterial toxins. For the sake, no doubt, of completeness, one chapter is devoted to a consideration of the symptoms of puerperal infection as a whole, and another long chapter to a description of the symptoms of the various forms of local infection. This arrangement necessarily leads to a considerable amount of repetition.

The chapters dealing with treatment, both medical and surgical, are distinguished by a judicious conservatism. The operation of curettage is recommended only when retained products cannot be removed effectually by the finger, and when the lochial discharge, after washing out the uterus, still remains abundant and foul-smelling. In considering serum treatment it is pointed out that with the present methods of preparing antibacterial sera a great deal of uncertainty attends their use, while with regard to vaccines the author holds that it is not yet possible to form a final judgment on their value. Posterior colpotomy, whenever sufficient, is favoured rather than abdominal section in cases of peritonitis; and hysterectomy is regarded as useless as a means of preventing death from septicæmia, in the absence of local lesions, in all forms of general peritonitis, and in thrombophlebitic infection. Indeed, the author comes to the same conclusion as most other writers on the matter—viz., that we are far from a solution of the difficulty of treating these cases successfully. We notice throughout the book the not infrequent mistake of spelling "aërobic" with a diphthong.

The book forms an excellent *résumé* of our present knowledge.

---

*Lectures on Biology.* By Dr. CURT THESING. Translated from the second edition by W. R BOELETER. With 6 coloured plates and 74 figures. London: John Bale, Sons, and Danielsson, Limited. 1910. Pp. 334. Price 10*s.* 6*d.* net.

THIS book consists of lectures which were given by Dr Thesing during the winter terms of 1905 to 1907 at the Humboldt Academy and the Urania in Berlin. Their avowed object is to show that it is no longer possible, having regard to the advances of modern research, to find complete satisfaction in being an out-and-out believer in the Darwinian or Lamarckian or any other theory. There are in all nine chapters. The first is entitled "From Thales to Lamarck," Thales being one of the seven wise men who attempted to establish a uniform principle of all phenomena. This original principle he sought in water. Erasmus Darwin is singled out as the first man who clearly enunciated the idea of evolution. The story is very readable, and well illustrated by reference to the evolution, uses, and modifications of limbs in different animals; while the proposition that it is the function which determines the form of all organs is supported by a study of animals of different classes but with the same life habits.

The second lecture deals with the "Phenomena and Conditions of Life." Proceeding from the dictum "All that moves lives," Dr. Thesing discusses motion in and by animals from the amœba upwards, deals with aeronauts and their ascents, deep-sea life, Regnard's researches and those of Bert on high atmospheric pressures; "gutter-fauna," e.g., bear-animalcules, apparent death, "dry-coma," the tenacity of life displayed by the lower organisms in the presence of cold, e.g., the survival of bacteria for seven days when exposed to a temperature of −190° to −225° C., all in turn receive attention. The cataplexy of W. Preyer is discussed, also Kircher's "experimentum mirabile" (1646) on a hen, and similar so-called hypnotic phenomena are introduced under the head of "Psychic Influences." We are told that the larva of corethra, a species of gnat, if placed in alcohol or osmic acid swims placidly about just as if it were in its proper element. Only after several days does this delicate little animal succumb to the effects of the poison.

The next subject is "The Forces of the Organism." At least twice there occurs this curious mistake when referring to Wöhler's synthesis of urea; it is given as "urine" (pp. 51 and 101). The term "fibre ducts" in bone must, we think, be a mistranslation. There is an interesting account of the architecture of bone. The author concludes that there is no need to assume the existence of a mysterious vital force in order to explain the purposeful construction of the bones or any other organs. One of the mysteries, however, will always remain hidden—consciousness, and so we are back at the famous dictum of du Bois Reymond "ignorabimus."

The fourth subject, "Building Stones of the Organic World," deals with cells and cell-life. Then follows an interesting chapter on the "Origin of Life," including the fantastic conceptions of Preyer and the cosmogenic views of the late Lord Kelvin. "The Evolution Theory," "Factors of Evolution," "Conservation of Life," and "Reproduction and Heredity" are pleasantly written sections rather in popular style. By way of illustrating phylogenetic relationships there are introduced hæmolysins, precipitins, and the "biological reaction." Other subjects considered are organic light production, artificial selection, colour adaptation, formative powers of light, symbiosis, transmission of

acquired characters, malarial parasites, mutation and Mendelism; and many other topics are interestingly discoursed on, the discussion including comments on the weakness of Darwin's theory of sexual selection.

The book is very readable and informing. There are some curious printer's errors, a few of which we note. "*Omni vivum*" for *omne*, "Erzengung" for Erzeugung, "scuttle fish" for cuttle-fish, "Remack" for Remak, "Columbia livia" for Columba. Eunuchs are described as having "very pronounced mammals."

---

*Applied Anatomy.* By GWILYM G. DAVIS, Associate Professor of Applied Anatomy, University of Pennsylvania, &c. With 630 illustrations. London and Philadelphia: J. B. Lippincott Company. 1910. Pp. 630. Price 24*s.* net.

THIS work is, as the author himself tells us in his preface, "an attractive volume," being well printed and well illustrated. The 630 illustrations are mostly very good; many are original, and many are taken from the well-known work of Professor Piersol. Some exceptions to the general high standard of excellency must, however, be noticed. Figs. 172 and 176 both show a strikingly confusing picture of the great vessels of the neck appearing to pass superficially to the clavicle to reach the thorax; and Fig. 532 can not be named a success. The author has adopted the BNA terminology, but he has not followed it entirely, and it would have been better if he had included the universal nomenclature for the position and direction of the parts of the body, for on p. 177, in one paragraph, the terms "below" and "beneath" are used in different and very confusing senses—"below" apparently signifying caudal, and "beneath" signifying deep.

Professor Davis has dealt with the subject of applied anatomy in a wide sense, and he has embarked on a discussion of all that is best in anatomy. As a result he has produced a very useful book, which, if not embodying much that is new, contains a clear and accurate account of what is generally accepted. In places the information is in some need of being modernised, and the description of the testicle and its descent should certainly be made to conform more to modern knowledge. The author makes repeated appeals to embryology for the explanation of various pathological conditions, but embryology cannot be considered as one of the strong points of the work, and it would seem a pity to introduce the subject when such assertions as that the malformations of the bladder are due to the failure of union of "the two lateral halves of the bladder" are made.

While we have perused this book with much interest a very disturbing train of thought has been brought about in us by attempting to follow to their logical conclusions some of the very curious speculations of the author. Take as samples two sentences, at random, the one from p. 216 and the other from p. 222. "If the forearm were lacking and the hand were attached to the end of the humerus it would still be a very useful appendage, far more so than the stump which is left after the hand has been amputated." And, "If the upper portion of the femur was like the upper end of the humerus, the lower extremity would be continually rolling in and out, making walking or running at least difficult, if not impossible." The attempt to appreciate these speculations has reduced us to a condition of anatomical nightmare that is difficult to shake off. We prefer the reasonings of an older generation of anatomists, and to admire an organ for what it is—the perfect outcome of its functions—rather than to attempt to picture the results of its removal to some other part of the body. Besides this peculiarity of speculation the author has many little tricks of phraseology which are inelegant and it may be noted that "insert" is usually considered to be a transitive verb in English, although the author uses it differently. These peculiarities do not, however, seriously detract from the general utility of the work.

---

*Hydrotherapy.* By GUY HINSDALE, A.M., M.D., Secretary of the American Climatological Association, &c. Illustrated. London and Philadelphia: W. B. Saunders Company. 1910. Pp. 406.

IN the introductory part the author deals with the *rationale* of hydrotherapy, and the effects of baths on metabolism and the circulatory and respiratory systems. The various affections in which water can be therapeutically applied are then considered in order, after which detailed instructions are given as to the application of the remedial measures. Then baths and douches are described, and the use of packs, compresses, and douches. Lastly, the administration of mineral waters internally, "crenology," or "crounotherapeutics," is discussed, though briefly.

Dr. Hinsdale alludes to the corroboration by recent authorities, such as Kisch of Marienbad, and Simon Baruch, of the old observations of Robert Pierce of Bath, in 1713, and James Currie, in 1798, that absorption of the fixed constituents of water does not take place through the skin, and therefore that "mineral waters, the analyses of which are quoted with such particular exactitude, are neither more nor less efficacious on that account," when used as baths. The value of the cold bath in pyrexial and hyperpyrexial cases is fully discussed and mention made of the early (and forgotten) pioneers in this method, such as James Currie, the English ship surgeon just alluded to, and Hiram Carson of Pennsylvania. Since its revival by Brand in 1861 it has been widely used, but H. A. Hare has always favoured substitutes for the Brand method since his experiences with typhoid in 1900, and sponging is now preferred to tubbing, unless the temperature rises above 102·5° or 103°F. The author insists that "as the main object of the cold bath in typhoid fever, or any other febrile disease, is *not* the reduction of temperature, ..... even in such a serious affection as sunstroke ..... the good effect of the use of cold water ..... is accomplished only by the vigorous stimulation of the nerve centres, inducing an added power to withstand toxæmia." There are, however, many tropical practitioners whose experience leads them to believe that the actual abstraction of heat is the only thing that is effectual, be the explanation what it may. A good account is given of therapeutic measures in cardiac affections, and the Nauheim baths and Schott treatment are well described and illustrated; the utility of bath treatment in insanity is also dwelt on. The third section is devoted to the technical details of the application of heat and cold in every form, hot-air and the electric-light treatment, sand and mud baths being described, as well as the various forms of water treatment.

The last section deals with the internal use of mineral waters—"crenology." It is generally understood that a natural mineral water has a distinctly greater therapeutic power than a water artificially prepared having precisely the same chemical constitution. The author considers that "it is barely possible that the recent discovery of radio-active properties in some of these waters may afford some explanation of these qualities." At Bad Gastein the radio-activity in "milligramme minutes" for 10 litres of gas issuing from the spring is stated as 79·20; the presence of the radium emanation is considered to be the main source of the beneficent quality of these waters. At Neusser's clinic in Vienna a large number of patients suffering from gout, rheumatism, neuritis, and diabetes have been treated with waters from the mines in Joachimsthal, near Prague,

the locality where the greatest quantities of pitchblende and radium salts are found. This water has much greater power than that of Gastein.

A very large amount of practical information is contained in this useful volume, with abundance of illustrations.

## LIBRARY TABLE.

*Conferences on the Moral Philosophy of Medicine.* Prepared by J. W. S. GOULEY, M.D. London and New York: The Rebman Company. Pp. 368. Price 6*s.* net.—This little work is primarily a text-book of medical ethics, and in many ways is a most useful compilation. Dr. Gouley, however, ranges over many subjects ancillary to ethics, and such subjects are necessarily treated in a superficial manner. He imagines an aspirant to the medical profession inquiring of his family physician as to certain "items of information concerning the profession whose ranks he hopes to enter." The family physician, called by Dr. Gouley "the sponsor," thereupon begins by giving the aspirant a short sketch of the history of medicine, including the erroneous statements that "the great colleges of Oxford and Cambridge in England were founded late in the ninth century," and that "the University of Paris was originally started towards the end of the eighth century through the influence of Alcuinus who became one of its first professors." Dr. Gouley is on much firmer ground when he discusses the career of the medical student and lays down rules for his behaviour when acting as interne and during his early days as a physician in practice. One of the most valuable portions of the book is the National System of Medical Morals, adopted in the year 1847 by the American Medical Association, a code of professional morals which is excellent. Among other points with which Dr. Gouley deals is that of the young physician as a writer. His precepts, we must say, are better than his practice. He advises the young physician to avoid fine writing, but on p. 77 of his own book we find the following sentence describing a hospital patient: "..... not being judged fit to retire to bed, fatigued as he was and suffering with some contusions from sundry blows and heavy falls caused by inco-ordinate muscular action due to many free libations of fluids which at first more than gladdened his heart, was ordered to disrobe and be cleansed." But although we cannot praise the manner of the book and have felt compelled to notice erroneous statements, yet the advice which Dr. Gouley gives as to conduct is in general most praiseworthy.

*Landmarks and Surface Markings of the Human Body.* By L. BATHE RAWLING, M.B., B.C. Cantab., F.R.C.S. Eng., Surgeon with Charge of Out-patients at St. Bartholomew's Hospital. Fourth edition. With 31 illustrations. London: H. K. Lewis. 1911. Pp. 96. Price 5*s.*—Mr. Bathe Rawling is to be congratulated upon the appearance of a new edition of his useful little manual of surface markings. That the issue of a fourth edition was already demanded is better proof of the utility of the book than any comments written by a reviewer. Some years ago Mr. Rawling had the good fortune to appreciate that a need existed for such a book, and he also possessed the ability to write the very book that met the need. Professor Bertram Windle had shown the road that should be followed when he published his "Handbook of Surface Anatomy and Landmarks," and Mr. Rawling has advanced along somewhat similar lines to a stage as near to perfection as it seems possible to go at the present time. The book gives in a short space all the important landmarks and surgical surface markings; it defines them accurately and illustrates them well; and it includes no additional matter such as may always be found in either the text-book of anatomy or the text-book of surgery. The material has been presented in the handiest form, both for revision for examinations and for reference in practice, and it is therefore not surprising that the demands of the student and the practitioner have made a fourth edition necessary so soon.

*Nisbet's Medical Directory, 1911.* In two parts. Part I., Directory of Medical Practitioners. Part II., The Local Directory. London: James Nisbet and Co., Limited. Pp. 838. Price 7*s.* 6*d.* net.—This handy and inexpensive directory is very useful for general purposes. The names are arranged in one alphabetical series without any local subdivisions; the local directory in its turn naming alphabetically every place in the world where a British registered practitioner resides, with the names of the medical men living there. In some instances that we have tested changes of address that occurred so lately as the middle of December are duly noted here.

*Ambulance Examination Questions: Being a Catechism on First Aid to the Injured and Sick.* By D. M. MACDONALD, M.D. Aberd., M.R.C.P. Edin. Fourth reprint edition. Bristol: John Wright and Sons, Limited. 1911. Pp. 24. Price 6*d.* net.—The best method of learning is by frequent questioning. In default of a questioner the student should learn to question himself. The difficulty he often finds in attempting to question himself is how to word a question without first thinking of the answer, which is a reversal of the method that should obtain. This collection of questions will help the first-aid student to test himself as an examiner would test him. The necessity for a fourth reprint is a testimony to its usefulness.

*Garden Foes.* Pp. 336. Price 2*s* 6*d.* net. *Carnations, Picotees, and Pinks.* Pp. 187. Price 2*s.* 6*d.* net. *Salads and their Cultivation.* Pp. 110. Price 1*s.* By F. W. SANDERS, F.L.S., F.R.H.S. London: W. H. and L. Collingridge.—A beautiful garden appeals to everyone and should engender feelings of peace and repose, but, as those who cultivate fruits or flowers know, beauty of perfection in the garden can only be attained by a ceaseless warfare against many enemies. In "Garden Foes" Mr. Sanders tells us how best to deal with the pests and diseases which are ever ready to spoil or destroy the cultivator's work in the flower, fruit, or vegetable garden and in the greenhouse. Chapters are also devoted to the foes of forest trees. In dealing with the process known as "cyaniding," the author is careful to point out the dangers of sodium cyanide, and the process, useful as it is, should certainly not be used by any but experienced persons. The chapter on "A Few Friends" should prevent those whose knowledge of entomology is small from destroying creatures which are useful allies to the gardener. Under miscellaneous pests the author includes the cat, and his ingenious devices for keeping these animals out of the garden will be appreciated by all who know by experience the damage which the cat can do to a seed-bed or among growing plants. The book is well illustrated, the notes are practical, and there is a good index.——The cultivation and propagation of the genus dianthus are dealt with in "Carnations, Picotees, and Pinks." This is a favourite group of flowers with amateur gardeners, among whom are many medical men, and Mr. Sanders has produced a book which very fully discusses the subject. Cross-breeding receives careful attention, and instructions are given for dealing with insects and other pests which are sometimes a source of trouble to the carnation grower.——The book on "Salads" includes some useful receipts.

UNIVERSITY OF OXFORD.—The electors to the Radcliffe Travelling Fellowship have reported to the Vice-Chancellor that they have elected Mr. E. P. Poulton, B.M., Balliol College, to the Fellowship. Mr. G. B. D. Adams, Christ Church, has taken the degree of D.M.

# THE LANCET LABORATORY.

## PERGENOL.

(THE SACCHARIN CORPORATION, 10, ARTHUR-STREET WEST, LONDON, E.C.)

THIS is an interesting product which brings the use of hydrogen peroxide of definite strength into easy practical application. Pergenol is a molecular combination of sodium perborate and sodium bitartrate. The compound in water immediately yields hydrogen peroxide by the interaction of the two salts. The statement is correct that when one part by weight of pergenol is dissolved in four parts of water a solution of peroxide of hydrogen of B.P. strength is obtained. The B.P. peroxide is required to yield from 18 to 22 volumes of oxygen when treated with permanganate. We found that one part pergenol dissolved in four parts of water gave 19–20 volumes of oxygen. It is evident that pergenol provides a simple way of applying oxygen, and lozenges are made for dissolving slowly in the mouth and tablets for preparing a solution for brushing the teeth or for gargling. It may be noted that as the result of decomposition boric acid appears also with the peroxide of hydrogen, so that there can be no question of the antiseptic as well as disinfectant value of the combination.

## VALIDOL.

(WIDENMANN, BROICHER, AND CO., 33, LIME-STREET, LONDON, E.C.)

Validol is an interesting compound of menthol and valerianic acid, which has been known for some time for its valuable sedative properties; it has been used for the same purposes in fact as valerian preparations with, however, certain advantages. More recently it has been found of value in sea-sickness. In this connexion we have read a considerable amount of testimony in its favour, the evidence being furnished in general by ship surgeons. Validol is a clear colourless liquid with a peculiar but not unpleasant odour and mild taste; it is readily administered in a small glass of wine, which aids its favourable effect. In severe cases validol camphoratum has given distinct benefit.

## "VAPOROLE" EPININE.

(BURROUGHS, WELLCOME, AND CO., SNOW HILL BUILDINGS, LONDON, E.C.)

Epinine is the synthetic hæmostatic which is said to possess all the remarkable physiological properties of the suprarenal principle. Being a synthetic preparation, it can be obtained in a particularly pure state, while the preparations of epinine are stable. Physiological tests have established that action on the blood pressure which is so characteristic of the suprarenal principle. Epinine is supplied contained in a "vaporole" or in a stoppered bottle containing 10 cubic centimetres.

## SHAKER SALT.

(AGENCY, COSENZA AND CO., 95, WIGMORE-STREET, CAVENDISH-STREET, LONDON, W.)

This is a clean white salt which keeps its fine dry powdery condition owing to its purity and to the fact that 1 per cent. of carbonate of magnesia has been added to it. It is free from lime salts, but contains traces of sulphate. It does not cake or "lump." The pleasant saltiness of its flavour is due to the absence of impurities. We found present 98·86 per cent. of pure chloride of sodium.

## STANDARD GERM FOOD.

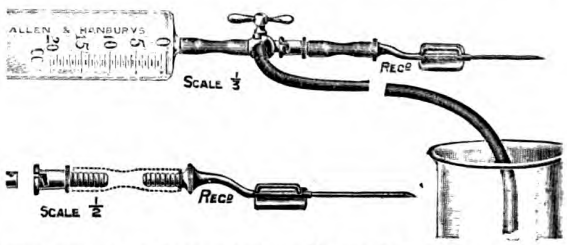
(H. W. MURFITT AND SON, DOWNHAM-ROAD, ELY, CAMBS.)

Analysis shows that this food cereal is rich in valuable dietetic constituents. Its composition suggests that it is rich whole wheat reduced to a fine powder and dried. The results of analysis were as follows: moisture, 4·50 per cent.; proteins, 11·90 per cent.; fat, 1·50 per cent.; mineral matter, 1·00 per cent.; carbohydrates by difference, 81·10. The mineral matter contains about half its weight of phosphoric acid. The food is entirely free from irritating branny particles. Practically 15 per cent. of the food is soluble in cold water, and this carries with it 0·80 per cent. of mineral matter. We regard it as a valuable cereal food presenting good dietetic points, and it can be employed in many agreeable ways, as with milk, for the preparation of a really nourishing article.

# New Inventions.

## A THREE-WAY SYRINGE AND CANNULA.

Messrs. Allen and Hanburys, Limited, of Wigmore-street, London, W., have constructed according to my suggestions a three-way syringe and cannula for the intravenous method of giving salvarsan. The needle, which is made of platinum with an iridium point, is only just over an inch in length, the advantages of a short needle being that it is not easily dislodged; is not likely to injure the vein or to perforate its walls; and the operator has more command over it. The point of the needle is on its under surface. Behind the needle is fitted a small plate, concave underneath, to lie more easily on the arm, and above it is a metal bridge through which a piece of tape can be passed and tied round the forearm or a piece of rubber tubing fastened by means of pressure forceps. The base of the needle then curves upwards and is fixed by means of a bayonet catch on to the three-way stopcock, which entirely prevents leakage. Between the catch and the needle there is a loose connexion made by thick rubber tubing. The advantage of this loose connexion is enormous, since any



movement is not transmitted to the needle, which not only prevents the needle becoming dislodged from the vein but avoids injury to the intima. The stopcock is fitted with a projecting piece on the right side, to which is attached some rubber tubing for the purpose of conveying the salvarsan solution to the syringe. The syringe, which should be all glass and of 20 c.c. capacity or more, fits on posteriorly by means of a small piece of indiarubber tubing, which enables any syringe to be used and again prevents leakage. To use the syringe the tap should be turned at right angles to the needle and some saline solution drawn up the long tube into the syringe, which should be emptied and refilled until all the air has disappeared. With the syringe full of saline solution the tap should be turned until it is parallel with the needle and some of the solution injected to remove any solid particle or air from the needle; then, with the stopcock open, the needle should be grasped by the plate behind it and inserted into a vein. The moment the needle enters the vein blood flows back into the syringe. The plate should then be fixed as above described and the tourniquet removed from the arm and some saline solution injected to be quite sure that no infiltration forms. The tap is turned back again, the tube transferred to the salvarsan solution, which is then aspirated into the syringe and injected. When the salvarsan solution is finished the tube should be transferred back to the saline solution, and finally a small quantity of this solution injected to wash out the vein and prevent any leakage of "606" into the subcutaneous tissue. To inject a dose of "606" in this way occupies about six minutes.

Harley-street, W. J. E. R. MCDONAGH, F.R.C.S. Eng.

## SELF-RETAINING MASTOID RETRACTOR.

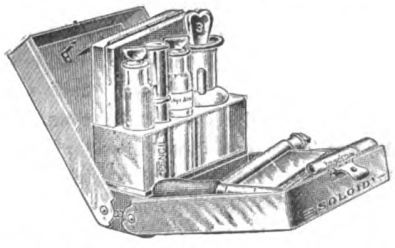
I HAVE for some time past tried to find a satisfactory self-retaining retractor, and having failed in the attempt have got Messrs. Mayer and Meltzer of Great Portland-street, London, W., to make one to my design. It is made in pairs, right and left. The body is constructed on the mouth gag principle, with ratchet action, one blade terminating in the oblong plate rounded off at one end to a point, and so constructed that, however deep it is inserted into the auditory meatus, it cannot injure the tympanic membrane. The opposing blade terminates in a row of hooks. The plane of the blades is such that when opened to the width of 1½ in. the action of the two blades is absolutely parallel. In practice it is used as follows. In the mastoid operation, after making the skin incision, elevating the periosteum and separating it from the posterior wall of the osseous canal, the retractor, with blades

closed, is inserted from above, the blade with the oblong plate being introduced between the periosteum and the posterior wall of the osseous canal and pushed well down. The retractor is then opened and the posterior lip of the skin incision engaged with the hooked blade. It is then further opened until the posterior lip of the incision is put on the stretch by the hooks, and all the structures in front are pressed against the anterior wall of the osseous canal by the plate blade, thus giving an absolutely clear view of the whole field of operation. The advantages of the instrument are: It retains its position throughout the operation; the one instrument is suitable for all sizes of meati; it mechanically prevents all oozing; it leaves both hands of the assistant free; and it takes the place of a skilled assistant. If the operator is attempting to conserve drum and ossicles, as in Heath's operation, the instrument does not leave him entirely at the mercy of a careless assistant.

CHAS. A. ADAIR DIGHTON, F.R.C.S. Edin.,
Honorary Assistant Surgeon, Eye and Ear Hospital, Myrtle-street, Liverpool.

## A BLOOD TEST CASE.

WE have received for inspection the "Soloid" Blood Test Case, No. 506, recently introduced by Messrs. Burroughs, Wellcome, and Co. of Snow Hill Buildings, London, E.C., which will prove of aid to the physician, since in many



more diseases than formerly was the case an examination of the blood is now made. Although the case is of pocket dimensions, the contents are so comprehensive as to include all the materials required for the speedy preparation of blood, pus, and tissue films. They comprise: one tube of "Soloid" brand Romanowsky stain (Leishman's powder), one 20 c.c. drop bottle, 10 c.c. stoppered phial of distilled water, 10 c.c. stoppered phial of methyl alcohol, 1 c.c. pipette, grease pencil, and vest pocket case containing six microscopic slides and Hagedorn needle in alcohol. Great skill and care have been exercised in designing the case, and it is of elegant workmanship.

## MEDICAL INSPECTION AND TREATMENT OF LONDON SCHOOL CHILDREN.

THE London County Council's arrangements for medical inspection and treatment were the subject of discussion—and condemnation—at a meeting called by the Fabian Society at Clifford's-inn Hall, Fleet street, E.C., on March 16th.

Sir VICTOR HORSLEY, who presided, said the London County Council system of medical inspection was a failure and did not fulfil the intentions of Parliament. The way the Council had dealt with the matter constituted a breach of faith with the nation. The staff of school doctors was inadequate and the organisation was ridiculous from a medical point of view. In support of the latter statement Sir Victor Horsley referred to the proposal to place Dr. Kerr under the control of Mr. Blair.[1] The parallel question of dental inspection had not been taken seriously into consideration by the Council, except for two "experiments" at Deptford and Poplar. As to treatment, Sir Victor Horsley declared that the only way of carrying it out was by means of school clinics.

Mr. R. A. BRAY, L.C.C., summarised very succinctly what the Council had done in regard to this question since it first came into prominence at the beginning of 1909.

Dr. H. BECKETT-OVERY, in the absence of Miss Margaret McMillan, discussed "What the Council ought to do," speaking strongly in favour of clinics, which, he said, were not, as some seemed to think, second-rate hospitals. It was essential to have an institution in close touch with the school, so that the coöperation of teacher, parent, doctor, and nurse might be secured. Most of the ailments from which the children suffered needed not so much treatment by specialists as constant attention by a nurse under the supervision of a doctor. With adenoids, for example, the removal was a minor part, subsequent physical and breathing exercises were more important. At Deptford the medical treatment of 5000 children was found to cost just over 2*s.* per head. Dr. Beckett-Overy's final point was that for a clinic the general practitioner could perform the best service and he could decide which cases should be seen by a specialist.

Dr. MARION PHILLIPS spoke of the incomplete way in which inspection was carried out. More time should be devoted to each case, the parent should be present, and it should be part of the school doctor's duty to give the parent some information as to the child's condition. The speaker dealt with the disadvantages of the present system of treatment through the hospitals, and said out-patient departments were totally unsuitable for the work. What was needed was a place to which the children could go regularly and get the nursing that home conditions made impossible.

The discussion was then thrown open, and many interesting points were raised. A parent aired his grievance that, though a contributor to various hospital funds, he had to pay for his children's treatment at voluntary hospitals. Another speaker urged that every effort should be made to influence members of the council to throw over the hospital scheme and institute clinics, and another that definite information as to the cost of clinics and the number likely to be required in London should be supplied to the Council.

Dr. HASTINGS supported school clinics from the point of view of the hospitals and their staffs. The hospitals did not want the routine work the present system gave them; they wanted the "interesting" cases.

Other speakers diverged into wider social problems, such as the need for improvement of the home conditions of the working classes.

In closing the meeting Sir VICTOR HORSLEY declared that the Board of Education ought never to have allowed the Council to embark on its present scheme.

# THE LANCET.

*LONDON: SATURDAY, MARCH 25, 1911.*

## The Epidemic of Measles in the Metropolis.

THE recent behaviour of measles once more throws into relief the remarkable tendency of the disease to display over and above its well-known predilections for certain seasons of the year, and its rise and fall in "minor waves," often of biennial rhythm, fluctuations in major waves of prevalence. These peculiarities of measles epidemics were first clearly described by Dr. B. A. WHITELEGGE, in a paper on "Measles Epidemics, Major and Minor," read before the Epidemiological Society in 1892. Dr. WHITELEGGE referred in this paper to the major waves of the "thirties," the early "forties," the "sixties," and the "eighties," and the years which have since passed by have seen the wave of the "nineties" (1892–1898), and now once more from 1909 onwards another major wave is being developed. As in PHARAOH'S dreams, the fat years are followed by lean years; but the major waves of measles cover, as a rule, a longer period than the seven years, "such as were never seen in all the land of Egypt for badness," and, moreover, in the case of the measles waves the general perturbation is disturbed by minor oscillations, for upon the upward and downward slopes of the major measles waves there are superimposed the (usually) biennial minor waves and the annual oscillations associated with seasonal prevalence.

Reference to the measles chart in Sir SHIRLEY MURPHY'S annual report for 1909 clearly shows that since the prevalence of 1897–98 London has enjoyed comparative immunity from measles for fully ten years; then in the early part of 1909 followed a notable exacerbation; and after the customary biennial interval there supervenes in 1911 the epidemic prevalence which is now just reaching its height. The number of measles deaths has, in fact, risen in the last four weeks from 131 to 136, to 175 and to 197, the last-named total being apparently the highest total weekly number of deaths from measles ever recorded in London. This very serious mortality is the more emphasised because other infantile maladies have in recent years shown marked abatement. Dr. WHITELEGGE in 1892 coupled measles with whooping-cough as representing zymotic diseases which had exhibited "little tendency to diminish their ravages." Whooping-cough, as Sir SHIRLEY MURPHY'S chart indicates, has never shown its head above the mean line (1841–1909) since the year 1890, and hence the development of the present major wave of measles brings that disease into a position of special prominence. The recent decision to utilise the hospitals of the Metropolitan Asylums Board for the treatment of certain cases of measles is an important one, and will be, no doubt, attended by considerable reduction of case mortality, and the children of the very poor will be far better cared for in these institutions than in their own homes. But a good deal still remains to be done with regard to securing earlier knowledge of the development of cases of measles, with a view to the adoption of measures of isolation and prevention.

A comprehensive and valuable report on measles was written by Dr. THEODORE THOMSON as long ago as 1896. This report discusses in a detailed way the use made of notification and of various preventive measures in a number of different sanitary areas. It is remarkable that hitherto so little practical effect has been given to the teaching of this report. The points emphasised by Mr. JOHN BURNS last week, in summarising conclusions arrived at by London medical officers of health at the meeting at the Local Government Board, were practically the same as those discussed by Sir R. THORNE 15 years ago in the final paragraph of his introduction to Dr. THOMSON'S report. They included notification, prompt and systematic visitation, further hospital accommodation, the judicious use of restriction of attendance at elementary and other schools, and the need for exclusion of children under five years of age during epidemic prevalence. In no single district in which Dr. THOMSON had made inquiry had all the practicable measures for the prevention of measles been systematically adopted. In how many districts have all these measures been "systematically adopted" in the last 15 years? Sir R. THORNE observed, in commenting upon Dr. THOMSON'S report, "Good result is not to be expected from adoption of any one of (these) several measures ..... each one ..... must be regarded as necessary and supplementary to the others." Dr. THOMSON'S report came nearly at the end of the major wave of the "nineties," and in the comparative calm of a succeeding ten years' interval it received less attention than was its due. Now that a major wave of measles is again upon us, Dr. THOMSON'S facts and conclusions will doubtless again be weighed and considered, and it may safely be predicted that the outcome will be a more practical one now than it was at the end of the prevalence of the "nineties."

## Tuberculosis in India.

WE have received a copy of a report on "How Tuberculosis is Spread in India," by Dr. J. A. TURNER, executive health officer, Bombay, which presents numerous interesting features. The modes by which tuberculosis, more particularly the pulmonary variety, is conveyed in Europe have been discussed times without number. Varying opinions have been expressed by different observers, and these opinions have occasionally had to be modified or abandoned. When the theory was first promulgated that pulmonary tuberculosis could be communicated by infection it was considered that dried sputum was the greatest danger—that is to say, that inhalation played the principal part. Another problem then arose—namely, whether human and bovine tuberculosis could be respectively communicated to cattle and human beings. In 1901 KOCH stated that tuberculosis could only be caused by food substance through a primary infection of the intestine. The work of VON BEHRING and others has shown, however,

that bacilli can pass through the healthy walls of the intestine and become lodged in the lymphatic glands and ultimately reach the lungs without causing any lesions in the intestine. Thus flesh and milk from tuberculous animals may also be an important factor in the causation of pulmonary tuberculosis. There is, however, a third source of infection which has scarcely received in this country the attention which it merits—namely, the possible contamination of food matters by individuals and animals the subjects of active tuberculous disease.

The sources by which tuberculosis is spread in India have not been so minutely studied, and Dr. TURNER'S remarks offer some valuable suggestions as to the differences which exist in the factors most potent in the dissemination of the disease in Europe and India respectively. In the first place he shows that the mortality from tuberculosis is higher in India than in England, and he then proceeds to briefly describe the methods of life led by the natives which especially tend to encourage the dissemination of the pathogenic bacilli. The first question he investigated was as to whether cows or buffaloes suffer extensively from tuberculosis in India, and he came to the conclusion that cattle are affected, but only to a slight extent. He then endeavoured to ascertain whether milk could be infected from human or bovine agencies, after it had been drawn from a healthy animal, by the habits and customs of the attendants or by the infected fæces of the tuberculous animals. His account of the manner in which the milch cattle stables, dairies, and milkshops in India are conducted is certainly not encouraging, and the habits and customs of the gowlis, their methods of milking the cattle and washing themselves and their milk vessels, leave much to be desired. The milk vessels are scoured with cowdung and dirt, the buffaloes and cows wallow in their excrement, and the buffaloes are washed at the same well that the milk vessels are cleaned at. Considering that the results of the Royal Commission on Tuberculosis (at the present time carrying out its investigations in this country) prove clearly that the fæces of the tuberculous cow are loaded with bacilli, the conditions referred to above show that there is a great possibility of the milk becoming infected. In addition Dr. TURNER says that it is a common thing to see the gowlis and stable attendants making their morning toilet at the well, and at the same place and with the same water they use for washing the buffaloes and milk vessels. A third point which Dr. TURNER investigated was as to whether human beings, especially children, could contract tuberculosis because of the intimate relation of the working classes with cows, bullocks, and buffaloes, and the enormous use which is made of cowdung, some of which must be infected. Cowdung mixed with urine and mud is used for plastering walls and floors and roofs of houses, and it is stored in the house. Even in large cities in India the cow and bullock are inmates of the dwelling-house, and all the cooking-pots and vessels used are scoured with cowdung from the street. From these observations it is therefore evident that the prevention of tuberculosis in India is intimately involved with the housing problem, perhaps even more intimately than is the case in our own country. Given healthy environment, the incidence of tuberculosis is lessened in India as elsewhere, while the climate must have some influence on the life of the bacilli, as the heat of the sun would kill the organisms if they are exposed to it. The dust of the streets where there is so much bullock traffic probably contains many bacilli, while the flies are an additional danger in conveying the infection. In addition, therefore, to the risks of infection from dried sputum, the habits of the natives undoubtedly tend to convey the bacilli, and the difficulties in the way of prevention must prove even greater than in England. Dr. TURNER makes many practical suggestions in relation to this matter, and shows the admirable sanitary work which is now being done in India to the best advantage.

A subject which is not discussed in this report is the influence of race. It is generally acknowledged that some of the dark races are especially prone to be attacked by tuberculosis. For instance, the negro is very susceptible, especially when removed from his own country, and an American observer, Surgeon KENNEDY, has stated that the mortality from this disease in a tribe of Red Indians living in the Rocky Mountains, in a splendid climate, amounts to 23 per cent. of the total death-rate. Similar observations from India and other countries on the lines of Dr. TURNER'S report would be of considerable interest and value. The diminution in the incidence of the disease in Great Britain which has accompanied the improvement in the general hygiene of the big cities is encouraging. Improvement in the dwelling-houses of the working classes and supervision of the milk-supply are all-important, and they would appear to be even more urgently required in India, where, moreover, the difficulties of compelling sanitary improvements are immense. The sections of the Act relating to the control of milk in Bombay are stated to be so defective that little control can be exercised over the sale of milk. Nevertheless, as much should be accomplished as possible. The opportunities for the contamination of the milk, even although tuberculosis does not seem to exist to a great extent amongst cattle in India, are so many that attempts must be made to guard against all such sources of infection, whether of bovine or human origin. If the milk-supply could be rendered more secure against pollution much would be done towards the prevention of the disease in India as with us. The nature of the climate tends to counteract in some measure the danger by inhalation, and if the risk of infection by food and milk could be lessened the mortality now caused by the disease would be doubtless considerably lessened. This is the main lesson taught, and now being put into practice by the executive health officer of Bombay.

---

LONDON SCHOOL OF TROPICAL MEDICINE.—Arrangements have been made for lectures on tropical subjects to be delivered to nurses at the London School of Tropical Medicine, Royal Albert Dock, E. Any qualified nurse may attend the course whether she intends proceeding abroad or not. Further information may be obtained from the Matron, Seamen's Hospital, Royal Albert Dock, E.

# Markham *v.* Abrahams.

THERE would appear to be an increasing tendency on the part of the public to seek for pecuniary damages on account of injury said to have been occasioned by the acts or defaults of unqualified persons who have attempted the discharge of medical or surgical functions. The recent action against Mr. BARKER the bone-setter was hardly concluded when that of MARKHAM against ABRAHAMS came on for trial and occupied the LORD CHIEF JUSTICE and a specia jury during the whole of two days, which might surely have been better employed. The plaintiff, a young lady who was preparing to be a science teacher, and had passed certain examinations with that view, became conscious of a defect of sight, and in 1907 she went, during his advertised "consulting hours," to the shop in Manchester of the defendant, who described himself as "an eyesight and spectacle specialist" and "a qualified optician of London," in order to seek advice. She was examined by an assistant and received spectacles; and during the next two years she paid further visits to the shop, usually seeing an assistant, and once seeing the principal himself. Her spectacles were changed on more than one occasion, but the result was unsatisfactory; and in 1909 she consulted Mr. CHARLES WRAY, who discovered her to be the subject of advanced conical cornea, and advised accordingly. She was compelled to abandon her intended profession; and it was maintained on her behalf that if the defendant had exercised reasonable care, and had been possessed of reasonable skill, he would have seen the case to be one of disease; that he had represented himself as a specialist and was bound to show reasonable care and skill as such; and that he could not avoid liability by saying that he was merely a tradesman engaged in the sale of spectacles. It was urged for the defence that the defendant did not profess to be a person able to diagnose and cure diseases of the eye, but was simply a maker and seller of spectacles. A chance customer came in and asked for spectacles to let her see better; she was tested, not for disease, but to find what spectacles would best assist her sight, and the defendant was only paid for supplying those spectacles, not for examining for disease. Mr. ENSOR, the defendant's assistant who first saw the plaintiff, said that he tested her eyes, found that she was astigmatic, and supplied her with spectacles which he told her would enable her to see better. He admitted that he had not made a study of the diseases of the eye; but it appeared, from the evidence of the plaintiff herself, that he had "used an instrument for throwing a strong light into her eyes." It is therefore manifest that she was examined with an ophthalmoscope.

The LORD CHIEF JUSTICE, in summing up, characterised the case as an extremely difficult one, and asked the jury whether they could say, "in view of the fact that opticians carried on a well-known trade, that they were under any obligation to discover disease?" The general framing of this question appears to indicate that his lordship would himself have answered it in the negative. With great respect for him, we would urge that the answer should depend entirely upon the acts and representations of the defendant or of his agent. If the plaintiff merely went into a shop where spectacles were sold, asked to see some, and selected a pair for herself, it is clear that the salesman would have no responsibility. But surely, if the plaintiff does not select for herself, but is "examined" in some way which she does not understand, and then has spectacles selected for her, and is induced to purchase them by a statement that they are what her condition requires, the salesman who attends upon her is clearly making a claim to special knowledge of the conditions governing sight, and ought not to be permitted to evade responsibility on the ground that he is a mere salesman, selling what his customer chooses to buy. During the considerable controversy which raged around the doings of so-called "opticians" a year or two ago, it was strongly urged on their behalf that they would always be able to detect "disease," and would be only too anxious to transfer any sufferer from it to the care of a competent adviser. We pointed out at the time that this claim was absurd; and in the case now under consideration the defendant himself said in the witness-box that he had "had no training or experience in diagnosing or dealing with diseases of the eye." The same was manifestly true of his assistant, Mr. ENSOR, who used the ophthalmoscope to test the plaintiff's refraction, because, as the late Sir WILLIAM BOWMAN pointed out 50 years ago, even the quite early stages of conical cornea are rendered conspicuous by the first glance at the eye through that instrument. If Mr. ENSOR had been a competent examiner he could not have failed to see by the shadow playing round the base of the cone that there was at least something unusual in the condition of the eye, something which, if it did not reveal disease to him, should at least have induced him to suspect it. We, therefore, think that he must have made a claim to the possession of skill and knowledge which, as a matter of fact, he did not possess, and had never had any opportunity of acquiring. From this point of view we entirely approve the verdict for the plaintiff, and at the same time we find no fault with the moderation of the sum of £25 awarded to her, although it is no sort of compensation for the injury she has sustained. The public must really be taught to use common sense, and to go to skilled advisers when they are in need of skilled advice. The case of Miss MARKHAM was one to which the maxim of "*caveat emptor*" should apply, and persons who are induced by the sort of patter that may be talked by unscrupulous shopmen to regard the talkers as authorities upon a difficult branch of medical science have only themselves to thank for any results which may ensue.

We regret to add that the trial gave occasion to something like a conflict of medical testimony, of a kind which might probably have been spared, and which could not fail to increase the difficulties of the judge and jury. Mr. WRAY, who was the first medical man to see the plaintiff, gave his evidence very fairly and clearly, and described conical cornea as a rare disease, occurring in perhaps one case out of a thousand, and he does not appear to have been asked about the possibilities or prospects of treatment. For the defence it was sought to establish that the disease was so rare that no recognition of it was reasonably to be expected, and so completely incurable that no ill-results could be

traceable to the circumstance that it had not been discovered. Mr. SYDNEY STEPHENSON (we quote from the *Times* report) said that conical cornea was a "very rare disease; he would estimate it at one case in 10,000 patients"; and that "in its incipient stage it was very difficult to discover"; while Mr. G. HARTRIDGE said that "there was no known treatment which would avail with conical cornea." Both gentlemen were, of course, giving accurate expression to their own experience or convictions; but we doubt whether ophthalmologists generally would be found to agree with either of them. Conical cornea occurs, as a rule, chiefly in adolescents of studious habits, and therefore does not occupy a large place in hospital statistics. PANAS quotes WHITE COOPER as having observed 194 cases in 209,000 patients, or 1 in 1077, figures so large that hospital cases must certainly be included in them. Mr. BRUDENELL CARTER contributed to THE LANCET in 1892 (Vol II., pp. 988 and 1374) a report on 10,000 consecutive cases of eye affection seen in private practice in London, and among these there were 20 of conical cornea, 5 males and 15 females, or 1 in 500 of the whole. There were 2431 simple refraction cases, to which those of conical cornea bore the proportion of 1 in 121·5. It is obvious that, apart from presbyopia, only the refraction cases and the early cases of conical cornea or of chronic glaucoma would be likely to find their way to a spectacle-maker's shop; and it may be inferred that an "optician" might be likely to see a case of conical cornea among every 130 or so of his younger customers. On the question of treatment, again, it is impossible to forget that the progress of conicity has, in a very large number of cases, been completely arrested, and the eye restored to fair and permanent usefulness, by the formation of a central cicatrix at the summit of the cone, and of a lateral pupil behind the portion of the cornea which most nearly retained its normal curvature. The excellent work of VON GRAEFE, carried on by Sir WILLIAM BOWMAN and his contemporaries, and materially improved upon in our own day by Sir ANDERSON CRITCHETT and by the use of the galvanic cautery, ought certainly not to have been ignored as an aid to the jury in estimating the amount of injury suffered by the plaintiff as a consequence of her reliance upon an adviser who was incompetent to advise. If she had sought surgical aid in 1907 she might have been enabled to continue the occupation which she has now been compelled to relinquish.

DEATH OF LORD AIREDALE.—When in the year 1904 the University of Leeds was inaugurated, among the first list of honorary graduates the name of Sir James Kitson found a natural position as being that of a man held in universal respect, fully alive to the responsibilities and duties of citizenship, generous in his views and in his actions, and a warm supporter and patron of the various charitable institutions of his native town, in many of which he had taken an active interest. His work as the head of a great industry made him an appropriate recipient of the degree of Doctor of Science. By the death of Lord Airedale, which occurred suddenly in Paris while he was on his way home from the Riviera, Leeds has to mourn the loss of one of its most distinguished public men and the University one of its earliest graduates.

* No trustworthy average.
† A day with at least 0·01 in.

The above statistics have been compiled from the annual summary of the weather, issued by the Meteorological Office, and afford on the briefest examination a good idea of the general character of the weather during the past year. It

will be at once observed that the only parts of the kingdom which did not suffer from a lack of sunshine were the coast of Lancashire and North Wales, Torquay, and some other resorts on the South-West of England, the North of Ireland, and one or two isolated localities elsewhere. The sunniest districts were the Channel Isles, the coast of Devon, and various resorts on the coast between Bournemouth and Felixstowe, while the most sunless were the City of London, and some of the large populous centres of the North, the absolute lowest record being 933 hours at Newcastle-on-Tyne. Compared with Torquay, the sunniest spot on the mainland, the figure at Newcastle is remarkable, showing an average of little more than 2½ hours per day against an average at Torquay of more than 4¾ hours. The greatest minus difference from the normal was at Jersey, which suffered a loss equal to more than half an hour a day, while at Blackpool, the only place with a very notable excess, there was a similar amount per day gained. In the metropolitan area there was a general deficit, except at Westminster, where the total number of hours exceeded the average by two. Over the kingdom as a whole the rainfall was in excess of the average, the plus value being very large in the Channel Isles, at many places in the south-west of England, and also at Bath. It may be remarked that for several years before 1910 the south-west of England had an annual fall considerably below its normal. The driest place given in the table is Clacton, with no more than 21·5 in., but Southend-on-Sea, Cambridge, and Whitby had an aggregate nearly as low, while the number of days with rain was smaller at Tottenham than in any other part of the kingdom. Many districts in England experienced at least 50 more days with rain than Tottenham, and at Cromer there were as many as 99 more rainy days. The frequency of slight rain in some parts of East Anglia was one of the most noteworthy features of the year. Very few localities in the wettest districts of Ireland and Western Scotland had rain on more days than Cromer, and yet at Great Yarmouth and Lowestoft the number was relatively low—only 170 at the former, or 85 less than at Cromer. Although the general character of the year was wet there were dry patches, especially in the centre and north-east of Great Britain, and also in the south of Ireland. In the latter region most of the recent years have been markedly deficient in their rainfall, and last year the largest deficit was at Roche's Point at the mouth of Cork Harbour, where the total fall was 5¾ in. less than the average.

## THE CONQUEST OF CONSUMPTION.

ONE of the most hopeful auguries for the eventual conquest of tuberculous disease is the increasing attention that is being devoted to this subject by public health authorities, philanthropic agencies, and administrative bodies. The various suggestions for the establishment of sanatoriums for poor consumptives, for compulsory notification, and for invalidity insurance are all indications of the increasing interest aroused in this subject. One of the greatest needs at the present time is a general awakening of the public at large to the main facts in connexion with this disease and to the great waste of human life and activities which it entails. Dr. A. Latham and Mr. C. H. Garland have recently published a new and revised edition of their book, "The Conquest of Consumption: an Economic Study."[1] In it they give an interesting and instructive account of some of the main problems in connexion with this disease, written in simple, non-technical language, and they also suggest a scheme for an efficient campaign against consumption, with some calculations of the probable cost. In our review of the first edition of this book we pointed out that the statistics of the mere monetary loss produced by tuberculosis among the wage-earning classes, as given by Dr. Latham and Mr. Garland, were simple but convincing. Consumption alone appears to cost the friendly societies more than £1,000,000 a year in sick benefits, and if to this are added the sums expended by means of Poor-law relief and by charitable agencies, such as special hospitals and sanatoriums, the total direct loss is estimated at nearly £3,000,000 a year. The subject of State intervention in this matter is discussed in an interesting and practical manner. The writers assert that it is the duty of the State to protect the population from this disease and to provide means of regaining the wage-earning capacity to those who fall victims. They estimate that of the total population of 43,000,000, only 2,000,000 persons are in a position to pay fully for treatment of this disease if they fall victims to it, and that of the remainder 13,000,000 are so near the poverty line that they would be quite unable to contribute towards their own treatment. Any successful scheme for dealing with this question must, they propose to demonstrate, embrace measures for the prevention of the spread of infection, the detection of the disease in its early stages, the provision of adequate sanatorium and home treatment, the support of the family when the breadwinner is away, and the question of after-employment. The essentials of the scheme suggested in this book are the provision of 30,000 sanatorium beds, the establishment of anti-tuberculous dispensaries, the allowance of a weekly payment of £1 to the individual patient's dependents, and some means of dealing with the hopeless and incurable cases. It is estimated that about 56,510 persons contract consumption every year, and that the total consumptive population reaches figures between 250,000 and 300,000, many of whom are in such an advanced stage that there is no hope of restoring them to lasting working capacity. The suggested scheme would provide adequate accommodation for 60,000 patients per annum if treatment at the sanatorium were to extend to six months. The estimated cost, based on certain actuarial calculations, would involve a capital outlay of £2,250,000 and an annual expenditure of £4,500,000, the latter diminishing as the good results of efficient and early treatment became felt. Dr. Latham and Mr. Garland defend the sanatorium system against the attacks which have been made against it, and especially against the suggestion that if some specific treatment more effective than the present tuberculin injection is discovered the sanatoriums will be unnecessary. They admit that the details of any comprehensive scheme, and the methods of raising the necessary money are questions to be worked out by statesmen, but conclude by stating that their endeavour has been to show the urgent necessity of both Government inquiry and State intervention. The problem is certainly one of national importance, and one which will sooner or later have to be faced. This little book is a practical discussion of the question and one which may be read with advantage by the public, for whose instruction it is primarily intended.

## WINKLES AND TYPHOID FEVER.

A CASE of typhoid fever having been traced to winkles taken from the river Ouse at Newhaven the urban council of that town prosecuted at Lewes petty sessions on March 14th a man who had been gathering the shell-fish from the river bank. An officer of the council approached the man while taking the winkles. He informed him that they were not fit for human food and asked him to give them up. The man declined, but consented to interview a magistrate who at once condemned the winkles as being

unfit for human consumption. The man still refused to give up the winkles, hence the summons and the police court proceedings. Defendant contended that if properly cleaned the winkles would be wholesome and of good flavour. The justices, however, thought otherwise and imposed a fine of 5s. The fine does not err on the side of severity, but it was the first case of the kind taken by the authorities under the Public Health Act. Authorities in general while looking after winkle gatherers might do well to give some attention to the condition of the river banks where winkles unfit for human consumption appear to thrive.

## BERI-BERI ON SHIPS.

BERI-BERI is met with at British ports on board ships under two different conditions: (1) on ocean-going steamers carrying Asiatic crews; and (2) on sailing ships, manned chiefly by Scandinavians, coming into port after a protracted voyage. Modern scientific investigation has brought forward very strong evidence associating the disease with the consumption of white polished rice from which there had been removed in the process of milling certain layers of the rice grain containing relatively large proportions of organic phosphorus; and that among the coolies employed on the plantations in the Malayan Peninsula this form of "phosphorus starvation" was the cause of beri-beri. An Asiatic crew on ship board among whom white or polished rice was the staple article of diet might be expected to suffer from the disease in the same way as the Malayan coolie on shore. But on the sailing ships the crews of which are Europeans, and where little or no rice is consumed, it was until lately more difficult to account for the appearance of beri-beri. These ships, owing to their slower progress, remain at sea for long periods, during which no fresh meat or vegetables can be obtained. Their dietary is of necessity made up largely of preserved food, much of it tinned. There has been brought forward recently evidence to show that in some of the processes employed for preserving these kinds of food the organic phosphorus is extracted or destroyed, and also that the growth of certain moulds on long-stored foodstuffs robs them of a proportion of their phosphorus. So that it appears that beri-beri may be produced by the same cause, not only among coolies in the East and Asiatic sailors aboard steamships, but also among European seamen on sailing vessels during long voyages. The deficiency of the necessary amount of organic phosphorus in the dietary produces wasting of nerve tissue which needs a certain amount of that element for its normal nutrition. It is not so long ago that beri-beri was regarded by some persons as an infectious disease, and this view still retains a hold upon the public mind. In THE LANCET of March 4th our correspondent in Ireland reported that three negroes had been landed at Galway from a barque which had arrived there from the West Coast of Africa, and that under the directions of the port medical officer the patients had been removed to the union fever hospital. Considerable anxiety, it was stated, had arisen from the presence of beri-beri in the town, the sanitary condition of which, it was admitted, left a good deal to be desired. Since this was published one of our readers has written to point out that the good people of Galway had no cause for anxiety, since the disease was not due to infection and could not therefore spread from imported cases; some of his own experience of the disease while abroad was also quoted by him in support of his opinions. It may be mentioned that on March 9th a question was asked in Parliament as to the isolation of these cases. In this connexion we may refer to a leaflet recently issued by the Marine Department of the Board of Trade, giving instructions on the subject of beri-beri, and intended primarily for the use of masters of steamships carrying Asiatic crews. After a distinct statement that beri-beri "is not contagious from one man to another," the leaflet goes on to describe the symptoms of the disease; the appropriate treatment is then indicated and the prophylaxis discussed. The theory of causation of beri-beri by white rice appears to be accepted by the Board of Trade, for it is strongly recommended that the ship's stores should contain no white or polished rice, but that yellow or unpolished rice should be substituted. At the same time an open mind is kept, for the leaflet states that the instructions issued by the Board of Trade will be liable to revision as the advances of our knowledge of the causes and effects of the disease may require. It is further mentioned that though many deaths from beri-beri are annually reported to the Board as having occurred on British vessels, these may not show the full extent of the mortality from the malady, since other cases which are reported as dropsy, paralysis, or heart disease may very probably be in reality deaths from beri-beri. The Board of Trade's leaflet should prove of great service in spreading knowledge as to the causation of this interesting disease and to the simple means for preventing it. To the masters of vessels carrying no surgeon the outlines of treatment given in the instructions should be of much assistance in the event of any of their crew being attacked.

## THE "DRY" WINE AND THIRST.

THERE is a curious lay impression that the so-called "dry" wine conduces to thirst, a literal meaning, no doubt, being associated with the word "dry." Applied to wine, the word "dry" really means, of course, free from juice which implies sugar. As sugar disappears in a wine by the continuance of fermentation the acid character of the fluid comes into evidence. Sugar, in fact, masks acidity, and the use of sugar in a lemon squash or on a fruit tart is resorted to for that reason. The acidity, however, is still there, but owing to the presence of sugar the acid is probably not so rapidly diffused, and therefore it does not have such an exciting effect upon the sensory nerves. It can hardly be supposed that because a wine is "dry"—that is, contains a minimum of sugar—it is thirst-producing. The "driest" of all wines is claret, and that is why so many people regard it as a sour or acid wine, there being practically no sugar present to balance the acidity. Sound claret is, as a matter of fact, the least acid of wines and the least sugary, but no complaint is made against it that it is thirst-producing. Champagne is just as acid as, if not more so than, claret, but contains more sugar, and it is champagne which is commonly accused of giving rise to a considerable thirsty feeling. The ingestion of much sugar gives rise to thirst, but a dry champagne contains not more than 2 per cent., and a reputed pint would not contain more than one-fifth of an ounce of sugar, which is less than many people use in a cup of tea or coffee. Another theory has reached us, which is that champagne gives rise to thirst because it is "limed" to make it "dry." Here again the suggestion is that the word "dry" connotes an absence of moisture or that lime absorbs moisture and leaves the consumer thirsty. The theory is manifestly absurd, and as a matter of practice lime is never found in the wine. It is, however, so common a matter of observation that champagne leaves a thirsty feeling, that there must be some reason why that wine should be distinguished from other wines in having this post effect. The sparkling quality of champagne, perhaps, coupled with the sugar contents, is probably a factor. Apart from the consideration that an alcoholic beverage is in itself a diffusible stimulant, its action is, no doubt, considerably accelerated when that

beverage is effervescing. Carbonic acid gas acts as a stimulant to the movements of the stomach and further aids the mechanical processes of digestion. It is probable, therefore, that dry sparkling wines are more readily diffusible than still wines, their effects are more pronounced on the functional activities, the fluid equilibrium of the blood is disturbed, its density is increased, and thirst tells this long tale.

## A RARE TYPE OF UNILATERAL HÆMOTOGENOUS INFECTION OF THE KIDNEY.

IN the *Yale Medical Journal* for January Dr. G. Emerson Brewer of New York has described an acute type of unilateral hæmotogenous infection of the kidney which he has studied since 1896. It is well known that in certain slight surgical lesions, such as boils, whitlows, and mildly infected wounds, and in some trivial medical diseases, such as coryza, bronchitis, and tonsillitis, as well as in severe infections, microbes enter the blood-stream. If their number is small, their virulence low, and if the kidneys are healthy, they may pass into the urine without causing any demonstrable lesion. If, on the other hand, their number is large, if their virulence is high, or if one or both kidneys are diseased, lesions are produced which vary from slight cloudy swelling or glomerular nephritis to complete destruction of the organ by purulent infiltration or necrosis. In the great majority of cases the early symptoms produced by this bacterial invasion of the kidney are comparatively mild, and are rarely differentiated from those of the primary disease or lesion. But as the renal disease advances a more or less characteristic group of symptoms is developed, such as increasing pyrexia, local pain and tenderness, pyuria, and leucocytosis. If unrelieved by treatment the patient becomes profoundly ill, and a diagnosis of pyelonephritis, pyonephrosis, abscess of the kidney, or perinephritis is easily established. The progress of the disease is gradual, but in the rare type now described, on account of the virulence of the infecting organism or the low resistance of the patient, the infection of the kidney is immediately followed by a toxæmia so intense as to resemble the onset of pneumonia or other acute infection, and the local symptoms are so overshadowed by the general symptoms that they are overlooked unless an unusually careful physical examination is made. If both kidneys are infected the patient, often without obvious cause, becomes violently ill with high fever, total suppression of urine, and rapid prostration, and dies in a few days from a combination of sepsis and uræmia. In the unilateral type, which Dr. Brewer thinks is the more frequent, death is due to sepsis alone, as one kidney continues to act. The following is an example. A woman, aged 28 years, was admitted into hospital suffering from a fracture of the leg and contusions. After three weeks, during which there was no evidence of disease, she suddenly became ill with symptoms suggesting a severe attack of influenza. The temperature rose to 104° F., and she complained of severe pain in the back and limbs. After two or three days tenderness over the right kidney and albumin and pus in the urine were found. Exploratory nephrotomy was advised but declined. The symptoms increased; she complained of constant aching in the right flank, had chills, became delirious, and showed every evidence of profound sepsis. Consent was finally obtained to lumbar nephrotomy. The perirenal fat was œdematous and the surface of the kidney was studded with deep, red, and elevated lesions. On incising the cortex the whole parenchyma was found filled with minute abscesses, of which the largest was 0·5 cm. in diameter. There was considerable hæmorrhage, which was controlled with difficulty. The incision was packed with gauze and the external wound was partly closed. The patient died after 12 hours. Dr. Brewer has observed 14 cases of this severe type of unilateral infection of the kidney. Of these, two were untreated, and death occurred in both within 12 days. Four patients were treated by nephrotomy and drainage, and all died soon after operation. Eight were treated by early nephrectomy and all recovered. He therefore strongly recommends this treatment, and says that to procrastinate or adopt other treatment is to invite disaster. But there are milder types in which less radical measures are indicated. These often simulate appendicitis, cholecystitis, or hepatic abscess. If unrecognised and unrelieved by treatment the disease progresses to the more definite and easily recognised text-book lesions, such as nephritic or perinephritic abscess, pyelonephritis, or pyonephrosis. The lesions are of the same general character as those of the severe type, but are fewer and involve less renal tissue. Stripping the capsule from the organ when the lesions are small, or a combination of this with the opening and draining of cortical abscesses or necrotic areas, is the best treatment. The following is an example. A woman, aged 26 years, complained of right-sided abdominal pain, nausea, headache, and fever. The temperature was 102° and the leucocytes numbered 19,000. Catheterisation showed that the urine from the right ureter contained a few pus cells, albumin, and blood. The right renal region was tender. Lumbar incision revealed œdema of the perirenal fat and a congested kidney with six indurated areas. They were incised and packed with gauze which was allowed to protrude through the wound. Only one contained pus. The renal pelvis was opened and appeared normal. Cultures from the pus showed the bacillus coli. Slow recovery ensued.

## CAISSON SICKNESS AND COMPRESSED AIR.

Dr. Leonard Hill recently read a paper on this subject before the Royal Society of Arts, giving an account of the experiments he had carried out with the help of first one and then another colleague—J. J. R. Macleod, C. E. Ham, M. Greenwood, F. Twort, and H. B. Walker. It used to be believed that exposure to compressed air immediately alters the distribution of the blood, forcing it inwards and causing a congestion of the viscera, which is suddenly and dangerously altered on decompression; and in spite of the writings of many investigators in France and Germany it was not until 1879, when Paul Bert published his great work "La Pression Barométrique," that the truth became generally known on the continent. But in England and America, where many great caisson works were initiated, engineers remained in ignorance of Bert's work and the mechanical theory held sway. In 1898 Dr. Hill began the experimental study of the subject in England, and by his experiments he established the truth of Bert's conclusions and overthrew the mechanical doctrines which were generally held here and in America. By a series of admirably contrived experiments on animals Paul Bert proved that compression caused no ill-effect until the amount of oxygen dissolved in the blood was sufficient to act as a tissue poison, that pathological accidents occur only after decompression, and are due to bubbles of nitrogen appearing in the blood and interfering with the circulation, and that these effects can be prevented by making the rate of decompression slow enough. In 1899 Lorrain Smith greatly advanced our knowledge of oxygen poisoning, and in 1907 Vernon made the important discovery that oil or fat exposed to air takes up in solution over five times the volume of nitrogen and oxygen that water does. On the direct effects of high pressure Dr. Hill had

some interesting remarks to make. As their experiments showed that dogs and cats and monkeys could be safely decompressed at a rate of 20 minutes per atmosphere from 100 lb., he and his colleague Greenwood went under pressure themselves to the extent of between 3 and 5 atmospheres, and were safely decompressed at the same rate. They found that there was no sense of pressure. The voice became very high-pitched and nasal in quality, whispering and whistling being impossible. They collected and analysed their alveolar air whilst in the caisson and found that the percentage of $CO_2$ fell as the pressure rose. Respiration is regulated by the quantity of $CO_2$ in the alveolar air, which, under normal pressures, is about 5 per cent. At a pressure of + 75 lb. it was found to be only 0·9 per cent. Within the limits of Dr. Hill's experiment the variation in pressure was such that the product of the percentage of $CO_2$ in the alveolar air and the number of atmospheres pressure was always the same, thus ensuring a constant concentration of $CO_2$ in the blood passing through the respiratory centre in the brain. In order to discover the best method of decompression, Dr. Hill and Mr. Greenwood studied on themselves the nitrogen saturation of the kidney. One of them drank two pints of water and half an hour later was compressed to + 45 lb. He then emptied his bladder and ten minutes later emptied it again. The urine filled a glass receiver which was sealed, and the gases were extracted from it afterwards by the gas pump. By this device samples of urine actually secreted in definite intervals, after a given pressure limit had been reached, were available for analysis. The results showed that the kidney, in a state of activity, is about saturated in 10 minutes. The observers were decompressed at a rate of 20 minutes per atmosphere, and their urine showed that desaturation of the kidney lagged behind the fall in pressure. Dr. Hill doubts the statement that the blood is completely desaturated during its passage through the lungs. The practical conclusions to which Dr. Hill comes are that while decompression times at caisson works are often too short, those tabled by the Admiralty Committee are too long, particularly if the men be persuaded to exercise their bodies during decompression. He finds that the "stage" method of decompression can be made fairly safe and is better than the uniform method for caissons. Fat and heavily-built men, and all men with defective circulation or pulmonary ventilation, should be excluded from caisson work, while it should diminish the tendency to bubble formation if fat food were avoided by caisson workmen and the diet limited to lean meat, bread, and vegetables.

## THE INFLUENCE OF DIABETES, GOUT, AND SYPHILIS ON THE TUBERCULOUS INFECTIONS OF THE HUMAN BODY.

AT a meeting of the Medical Society of London held on March 13th Dr. Nathan Raw read a paper on the Influence of Diabetes and Gout on the Tuberculous Infections of the Human Body. Diabetes has long been recognised as predisposing to pulmonary tuberculosis, although the former disease is also associated with bronchitis, pneumonia, and gangrene of the lung independently of tuberculosis. The resistance to microbic infection or activity is considerably lowered in diabetes, and particularly so to the action of the tubercle bacillus. In former years the lesions of the lungs in diabetes were ascribed to a non-tuberculous inflammatory process. Virchow was one of the first to demonstrate the true tuberculous character of the pulmonary affection, but the exact connexion of the two remains doubtful. Beyond the general statement made above—viz, that the resistance in diabetes to certain lung affections is lowered—Dr. Raw considers that the blood plasma is the determining factor in the growth and inhibition of bacterial infections, and supports his contention by experiments he has made with blood from cases of diabetes and gout. It is generally known that gouty individuals rarely suffer from tuberculosis, and Dr. Raw relates the results of growing pure cultures of tubercle bacilli on media which had previously been mixed with the blood of patients suffering from this disease. After four weeks' incubation, it appears, no growth was observed, and even after eight weeks there was only to be seen a slight irregular growth on the surface of the medium without any distinct clumps of bacilli. At the same meeting of the society Mr. D'Arcy Power read a paper on the Influence of Syphilis on Tuberculous Infections of the Human Body, in the course of which he arrived at some interesting conclusions. This is a wide subject and it requires further research, for the two diseases may occur under widely different conditions. That syphilis may predispose to tuberculosis is probable, and also acquired syphilis may render tuberculous lesions more active, but the influence of tubercle on syphilis has not been, as far as we are aware, clearly demonstrated. If medical practitioners who in the course of their duties are frequently brought into contact with such cases would record their observations some interesting results might be obtained. There is also here a large field open for laboratory research, which would materially help to clear up the uncertainty which now prevails.

## DEATH OF PROFESSOR JOHN ATTFIELD, F.R.S.

THE announcement of the death of Professor John Attfield, F.R.S., will be received with very genuine regret by members of the medical, chemical, and pharmaceutical professions. Professor Attfield was for a good many years the adviser on pharmaceutical subjects to the General Medical Council, and in the 1898 edition of the British Pharmacopœia the Council expresses its indebtedness to him both for his scientific and for his literary services. He had at one time a large consulting analytical practice, and was an authority on questions of food and water-supply. His book on "Chemistry, General, Medical, and Pharmaceutical," is still a favourite, particularly with pharmaceutical students. He was professor of practical chemistry at the Pharmaceutical Society from 1862–96, his appointment previously being that of demonstrator of chemistry in St. Bartholomew's Hospital.

## SMALL-POX IN BURY AND WIGAN.

A LOCAL correspondent writes: "Two new cases of small-pox were notified in Bury on March 14th, and the patients were removed to the Ainsworth Hospital. Two further cases were reported on the 15th, making nine in all. On the same day the operatives at the cotton mill where all the sufferers were employed refused to start work. The mills are being disinfected, and there is a great demand for vaccination. A further case, a man employed at the same mill, is suspected of having caught the infection. In view of the suspected origin of the outbreak the medical officer of health has recommended that all cotton operatives should be vaccinated or revaccinated. Three more cases are reported at Wigan, where there are now five persons suffering from the malady. The first patients removed to the local sanatorium were two men who had been employed at a mill at Ince. The latest victims are the wife and daughter of one of the men and a married woman who had visited the house. The vehicle of contagion is believed to have been the imported cotton. So far, only one case of small-pox has been notified in Liverpool. Liverpool is, fortunately, one of the best

vaccinated cities in the kingdom, the 'conscientious objector' being there a *rara avis*." Under date March 21st he adds: "Since writing the above, I am informed that on March 16th eight new cases were reported at Bury, bringing the total to 20 since the first case was reported on March 7th. The outbreak appears to be rapidly assuming epidemic form. The woven cloth warps and wefts in several of the looms at the mill have been destroyed, and some 3000 pieces of finished cloth have been disinfected at the Ainsworth Hospital. All the patients are being removed to this building, where there is permanent accommodation for 35 patients, but foundations are in for temporary buildings by which in case of necessity the accommodation could be more than doubled." Only two new cases have been notified this week.

## A PLEA FOR CHEESE.

WE have received from Major R. J. Blackham, D.P.H., R.A.M.C., a copy of a lecture on "Cheese in History, Commerce, and Dietetics," which contains many sensible observations in favour of including more cheese in the daily diet. After summing up the virtues of cheese he says very rightly that against its good qualities the only defects that can be urged are that it may be indigestible if improperly eaten or cooked, and that there is a popular prejudice which associates meat with wealth, cheese and oatmeal with poverty, and bread and water with criminals. He reminds us that cheese is nutritious, very wholesome, very cheap, keeps well even in the tropics, is a very compact and portable food, and it need not be cooked. He appeals to his medical colleagues to join in the crusade against the over-eating of meat and to induce their patients, occasionally at least, to substitute for the "meretricious attractions of the ill-cooked joint" the wholesome and far more nutritious qualities of good, sound, English or colonial cheese. Medical men, he adds, should certainly encourage amongst the so-called better classes the inclination towards the "simple life" which has now become more than a mere fashionable craze, for in matters of health a simple dietary has, in these strenuous days, much to recommend it. In cheese we possess a substitute for meat foods of value in domestic economy, but the considerations have to be borne in mind that to not a few cheese tends to become a monotonous diet and with some it will not agree. Flavour is of considerable physiological importance in dietetics.

## TAKA-DIASTASE IN THE TREATMENT OF DIABETES MELLITUS.

Dr. E. J. G. Beardsley, writing in the *Therapeutic Gazette* of Feb. 15th, quotes with approval a remark to the effect that the best way to learn all about a disease is to see its development in a friend. This was his own experience with diabetes mellitus; the futility of our present available means of treatment was borne in upon him when he was confronted with the symptoms of this disease in a friend. As a result of several conversations with Dr. H. A. Hare he determined to test the effect of administering taka-diastase in the form of powder. The patient, a man aged 32 years, had been under treatment by various physicians on both sides of the Atlantic for about three years. The amount of sugar had varied from 3 to 9 per cent. When Dr. Beardsley first saw him he was very ill, unable to get up, troubled by intense hunger and thirst, passing about 200 ounces of urine per diem, and suffering from diarrhœa. The urine contained 4·6 per cent. of sugar with a large amount of acetone and diacetic acid. He was given taka-diastase in 5-grain capsules, one after each meal and at bedtime. During the first 24 hours of this new treatment, the urinary excretion fell to 130 oz, the sugar fell to 3 per cent., and the ketone products also decreased. This improvement continued, the output of sugar remaining at 3 per cent., although the total excretion of urine fell to 85 oz., and a much freer dietary was being permitted. After three months' treatment the excretion was still about 80 oz. a day, and the patient had put on weight and felt better in every way. Dr. Beardsley has had good results in four other cases: in one man, aged 36 years, a non-diabetic glycosuria disappeared completely; another man suffering from diabetes was so much improved that he gained 6 lb. in as many weeks, and went back to his work as a carpenter; a third patient (a woman aged 42 years, with 1·5 per cent. of sugar and intense pruritus vulvæ) was relieved of the itching, although the sugar rose to 3 per cent.; while the fourth, a case of alimentary glycosuria, was also greatly relieved. Dr. Beardsley found in all these cases that improvement ceased if the drug was stopped, but that no untoward effects were traceable to its administration. The number of cases is small, but in so desperate a disorder as pancreatic diabetes anything that holds out the faintest prospect of improvement is worthy of extended trial, and there is no doubt that other physicians will watch with eagerness, and we hope without disappointment, the effects of taka-diastase.

# MOTORING NOTES.

BY C. T. W. HIRSCH, M.R.C.S. ENG., L.R.C.P. LOND.

### *The Material for Petrol Tanks.*

RECENTLY a colleague consulted me on a peculiar trouble that he had with his car. It was a good car, of a well-known make, and when going went well, but at times the carburettor absolutely refused to flood, with the consequence that the car on such occasions also declined to go. At first the body builder was credited with the blame; it was alleged that the tank was too low, as the petrol was gravity fed; the petrol plug was tapped to take the end of the tyre pump, but even when the petrol was thus pressure-supplied at times the carburettor was starved. A double petrol pipe was then fitted, the pipes were moved, and even a larger one was introduced, and all without avail, and then the cause was indirectly ascertained by the fitting of a new tank. The old one was of galvanised iron, the new one of brass; with the change the trouble vanished. The galvanisation of the iron tank had worn off and the iron on the tank's mucous membrane or interior had scaled, and little bits of these foreign bodies entered the petrol supply-pipe and so acted like a calculus in the ureter, and stopped, until they were passed, the passage of petrol. The deduction is therefore that these vessels for storage of petrol should be made of either copper or brass, and any way not of galvanised iron. On most good cars I understand that this is the rule, though on some of the cheaper ones galvanised iron is employed.

### *Is the Petrol Tank an Integral Part of the Chassis?*

This question arose out of the case just mentioned, as it was suggested that the petrol tank on the car in question may have been changed. I am given to understand that the petrol tank is an integral part of the chassis of a car, and if a chassis is bought the original petrol tank that was on the chassis at the time of purchase of the car is included and should go with the car.

### *Retreading of Tyres and the Proposition of the Challenge Rubber Mills.*

Without question the most important item in the running of a car is the cost of tyres, and a point that frequently has to be settled is, Shall an old tyre be thrown away, or sold as old rubber, or is it worth retreading? If the tyre is much worn or has had a burst the mileage to be obtained from the repaired cover often makes the expenditure less remunerative than the cost of a new tyre would be. To meet this, the

Challenge Rubber Mills of Eagle Wharf-road, City-road, London, N., offer that if a worn or burst tyre is sent to them they will report if it is worth retreading, and if not they are agreeable to select from their huge stock of second-hand covers one that will stand retreading, and which they will guarantee will give good service, and this they will do for the cost of the new tread, exchanging the scrap cover without charge; or they will accept the old cover in part payment for a sound second-hand cover that does not require a new tread. This firm have large works, where every process, including that of the preparation of the retreading compound, is carried out; they are thus in a position to give good workmanship and quality of material, and from what I have heard from motorists who have had tyres retreaded there this proposition is well worthy of the fullest consideration. This firm also market an all-rubber inner tube which they guarantee up to 10,000 miles if run within 12 months, and during that period they repair punctures free and also reseat valves. Their combination tube and shield is reinforced on all sides except the tread, which is of all rubber for the purpose of expansion and resiliency, and this is protected by a rubber-covered fabric shield, which is light and easy to fit and is practically unpuncturable.

*The Licence for Electric Cars.*

Under the terms of the Treasury regulations any car deriving its motive power otherwise than from an engine worked by cylinders is deemed to be of a horse-power exceeding 12 but not exceeding 15, which means a tax of £4 4*s*. to the general public. Recently at the Marylebone police-court an owner of an electric car which was supposed to be of 4½ horse-power was summoned for only taking out a licence for £2 2*s*., while under the regulations it should have been one for £4 4*s*. It was, however, suggested that the unit of horse-power for the purpose of any rate of duty under the Finance Act of 1910 shall be calculated in accordance with the regulations made by the Treasury for the purpose, and it was maintained that the Treasury should make regulations by which the unit of horse-power could be worked out, and that any way in this case it was not fair to fix an arbitrary and excessive horse-power. Finally, the representative of the Excise Department of the London County Council withdrew the summons. Probably a decision will eventually be arrived at under which owners of low-powered electric cars will not have to pay as if they had a 12 to 15 h.p. car.

*A Useful Fixed Cut-out Switch.*

Frequently, if one of the cylinders on a multicylinder car is missing fire, a screwdriver or spanner is used to cut out each plug in turn, and thus the one that is giving trouble is ascertained. In doing this it is possible to get a shock, or even if this is avoided the make-shift method is rather clumsy. Messrs. Brown Brothers of Great Eastern-street have introduced a well-insulated little device, known as the Tangye cut-out switch, which is inexpensive, and is intended to be permanently fixed in position, one on each plug, and by this means, without any trouble, the plugs can each be separately cut out and the offending one detected.

*The "Motor" Doctor's Edition.*

Our contemporary the *Motor* devoted its issue of March 14th especially to the requirements of the medical profession in things motoring. The advertisers entered into the spirit of the issue, one of them catching attention with an opening remark upon "cerebral tumour." Any professional man contemplating the purchase of a car may get some useful information from the number in question.

*Free Motor-car Insurance Policy.*

In connexion with their motor tyres, Messrs. Pirelli, Limited, of 45, Basinghall-street, London, E.C., are offering a free motor-car insurance policy against accidental damage to the car and accessories, accidental damage whilst in transit by road or rail, wilful and malicious damage, and cost of carriage to or from repairers, &c. The policy is issued by the London and Lancashire Life and General Assurance Association, Limited.

# THE REGISTRAR-GENERAL'S ANNUAL REPORT FOR 1909.

## I.

THE seventy-second annual report of the Registrar-General of England relating to the year 1909 has recently been issued by H.M. Stationery Office. It will be remembered that the corresponding report for 1908 appeared within 12 months of the close of that year. The needful preparations for the census taking of next month must, however, have absorbed a large share of the time of the Registrar-General's staff, and in such circumstances the impracticability of completing the volume within a similar period may reasonably be accounted for.

In his prefatory remarks Mr. Bernard Mallet draws attention to certain changes now introduced in the form of his report. For several years past the several sections dealing with the registration of births, deaths, and marriages have been authenticated by the Registrar-General himself, whilst the analysis of causes of death has formed the subject of a letter addressed to his chief by the medical superintendent of statistics. In the present volume the Registrar-General contents himself with a brief address officially presenting the report to the President of the Local Government Board and discussing the changes that will appear in the present and in future numbers of the series. The statistical portion of the report is dealt with in detail by Dr. T. H. C. Stevenson, the statistical superintendent, who thus becomes virtually responsible for the accuracy of the entire report. In the Registrar-General's opinion this arrangement will enable the statistics to be treated as a whole, and in a clearer and more consecutive manner than before, the overlapping and repetition in the mortality sections which, under the old system, were unavoidable now disappearing.

*Improvements to be Made in Future Reports.*

On the score of practical utility English national statistics are sometimes adversely criticised, because of the lack of uniformity among publications issued by the various State departments. From circumstances beyond departmental control the vital statistics of the General Register Office must be regarded as in one sense defective because of want of correspondence between the registration areas to which they relate and the administrative areas which have been established throughout the country for sanitary purposes. Sir William Dunbar, in particular, always deplored the persistence of this anomaly during the period when he was Registrar-General, and several of his most recent reports attest the fact that in his time much was done to adjust anomalies of this kind which could not be entirely removed except by the amendment of statute law. Mr. Mallet may be congratulated on being able to record that since the issue of his previous report all administrative difficulties have been overcome and that certain far-reaching improvements will be introduced into the report for the first year of the new decennium. The Registrar-General informs his readers that in considering the changes now decided upon his main object has been to secure coördination between the statistics published by his authority and those of other departments of the State, as well as those of other countries, thus rendering the official returns of greater use than before, not only to those engaged in public health administration but to scientific inquirers generally.

Among the changes above alluded to the most important would appear to be the substitution in the annual reports of local government administrative areas for registration or Poor-law counties and districts. For reasons given in a previous report[1] the statistics must continue to be collected for registration areas as long as the present Registration Act remains in force; but after the close of 1910 these returns will be rearranged in the central office and published according to administrative areas. It is believed that by this and certain other modifications in the annual report the statistics will be brought into line not only with those of the annual summary, but also with the statutory returns of the local sanitary authorities furnished to the Local Government Board.

Another desirable change promised in future reports is the

[1] Registrar-General's Seventy-first Annual Report (1908), p. vi. (Cd. 4961).

distribution of births and deaths to the districts to which the mothers or the deceased persons respectively belonged. This method of distribution has not hitherto been adopted in the annual reports, although it has been partially carried out in the weekly and quarterly returns and in the annual summary, on the authority of unverifiable returns furnished by the local registrars. In order to secure the necessary uniformity of distribution in the national statistics arrangements have been made for reference to the districts to which they belong of all transferable deaths and institution births, and this rule will be observed both in the Registrar-General's official tables and in the tables prescribed by the Local Government Board for use by medical officers of health. The necessary information will be collected by the central office and furnished by that office to the local authorities throughout the country. Mr. Mallet acknowledges the readiness with which county medical officers of health have promised their coöperation in effecting this distribution in their own counties.

The need for rearrangement of local returns in order to publish them under administrative areas has necessitated recourse to the card system, and to the complementary device of electrical sorting, the cost of which in the present case has been materially reduced by the circumstance that the card system has already been adopted for the purpose of the approaching census. Lastly, the Registrar-General expresses the belief that the application of the foregoing methods to the elaboration of vital statistics will greatly increase their flexibility and their value, inasmuch as it will facilitate the making of special inquiries necessary from time to time for official purposes, or called for by scientific investigators outside.

*Estimates of Population in Intercensal Years.*

As the interval increases since the last census the trustworthiness of population estimates becomes annually more doubtful, whatever methods of estimation be employed. This applies more especially to estimates of the population of the large city areas, which have been considerably affected since 1901 by improvements in the means of transit. Like most of its predecessors, the coming census will almost certainly show that the previous rate of increase has by no means uniformly been maintained in the chief urban centres, but that the rate of increase has been accelerated in their outlying portions. The ultimate effects of these changes will, of course, depend upon the extent to which the municipal area of a large town represents the actual residence of the population in each case. It is obvious that the only remedy for the present uncertainty as to population lies in the more frequent enumeration of the people. The staff of the General Register Office is fortunate in possessing in Mr. A. C. Waters, F.S.S., a statistician of large experience and of conspicuous mathematical ability. By his many valuable contributions to the Royal Statistical Society Mr. Waters has shown his deep interest as well as his skill in the examination of statistical problems relating to natality and to mortality. The high value of his services has been repeatedly acknowledged by his official chiefs, and by none more appreciatively than by Sir William Dunbar, who in his last annual report as Registrar-General particularly directed attention to Mr. Waters's methods for estimating local populations in intercensal years. For years succeeding the date of the coming census this method will replace that at present in use for the estimation of local populations in the administrative areas of England and Wales.

*Decline in Marriage-Rate.*

The graphic representation of statistics is a feature of the Registrar-General's recent reports to which we have alluded approvingly on several previous occasions. In the present report this method has been considerably extended, and although to some persons the older tabular method appeals more strongly, we are convinced that the majority of readers will appreciate the further development of the graphic method. The first diagram in the present report is conclusive as to the still persistent depression of the English marriage-rate. From this diagram we learn that the rate of marriage, based on the total population at all ages and of both sexes, does not adequately express the real decline that has taken place. Accordingly an additional curve is inserted showing the rate in terms of marriageable persons living; and, thus estimated, the rate in all but one of the last 29 years is shown to have been below the rate of 1876–80, taken as a standard.

*(To be concluded.)*

# MEDICINE IN THE ENCYCLOPÆDIA BRITANNICA.

## IV.[1]—*Food and Drugs.*

THE History of Adulteration affords the theme of one of the most interesting and best written articles turning upon food questions in the Encyclopædia. It is contributed by the well-known analyst, Mr. Otto Hehner, who shows a very intimate acquaintance with the subject, not merely from the analyst's point of view, but from the public point of view also. Mr. Hehner has worked hard at the administrative side of the subject, and what efficiency the present Act possesses may be attributed to the clear representations which he amongst others has made from time to time before Royal Commissions and Departmental Committees. Mr. Hehner was at one time associated with Dr. Hassall, who in the "fifties" (that is to say, before any Food Act existed) was commissioned by the Founder of this journal to extend his microscopical methods of examination, coupled with chemical analysis, to articles of food in general. The result was that, as Mr. Hehner writes, "for a period of nearly four years reports of THE LANCET Analytical Sanitary Commission were regularly published, the names and addresses of hundreds of manufacturers and tradesmen selling adulterated articles being fearlessly given. The responsibility incurred was immense, but the assertions of the journal were so well-founded upon fact that they were universally accepted as accurately representing the appalling state of the food-supply." Here was the beginning of a serious attempt to protect the public against poisonous and fraudulent practices connected with food-supply. In consequence of THE LANCET'S disclosures a Parliamentary Committee was appointed in 1855, the labours of which resulted in 1860 in the Adulteration of Food and Drink Act, the first Act that dealt generally with the adulteration of food. From that time legislation gradually advanced until the Act which is now in force passed in 1899. As Mr. Hehner points out, however, this was not a comprehensive Act superseding the previous Acts, but was an additional and amending one, so that at the present time four food Acts in reality run parallel and are together in force, rendering the subject from a legal point of view one of extreme complexity. Still more unfortunate was it that, while the Act of 1899 was made to embody the most important recommendations of the Food Products Committee, one very serious exception was made—viz., the appointment of a board of reference which should deal with difficulties as they arose, guide analysts and public authorities in fixing limits for articles (other than milk and butter), and take up such important questions as the use of preservatives and colouring matter in food. The Act, however, recognised "the importance of a regular and conscientious control of the public food-supply by the local authorities," because certain sections in it gave to the Local Government Board and the Board of Agriculture "a roving commission to see that the Acts are properly enforced throughout the kingdom so as to apply the Acts more equally throughout the country than heretofore, and in default of local authorities carrying out their duties empower the Government departments mentioned to execute and enforce the Acts at the expense of the local authorities." The Local Government Board has recently taken a practical interest in this matter and has created a new department presided over by an official inspector of food, and the department has added to its resources an analytical laboratory. In spite of imperfections in the Act the effect of the application of the food laws has been entirely beneficial. This is Mr. Hehner's view and we endorse it entirely.

In his references to the working of food Acts elsewhere Mr. Hehner deals chiefly with the National Pure Food Law of 1907 in the United States, which represents, perhaps, the strongest legislative step that has so far been taken in connexion with food-supply. This law provides an elaborate set of food definitions and standards, so that for each of the more important articles of food an official definition of its nature and composition has been established. These definitions are, he considers, of the utmost value to food officers, manufacturers, and merchants, not only in the United States but throughout the world.

[1] Articles I., II., and III. were published in THE LANCET of Feb. 25th (p. 530), March 4th (p. 609), and March 11th (p. 692), 1911, respectively.

The paragraphs on particular articles adulterated will be useful in conveying to the public in simple terms in what direction the practice of adulteration is a favourite field. In the note on beer there is an obvious misprint; bisulphate of lime should be bisulphite. In the article on spirits the writer refers to the report which appeared in THE LANCET in 1902 on "Brandy, its Production at Cognac and the Supply of Genuine Brandy to this Country," which, he says, served as a stimulus to public analysts to analyse commercial brandies, and convictions of retailers for selling so-called brandy followed. It may be remarked that, while that report pointed out what were the chemical characteristics of Cognac brandy, it did not lay down figures in terms of ethers with the view of setting up a standard. The point under consideration was whether the brandy sold in this country as Cognac brandy was entitled to the description Cognac. In another section is a good article on brandy by P. Schidrowitz.

We quite endorse the view of the writer as to the adulteration of drugs. It is satisfactory, he says, to record that but very few of the great number of drugs included in the pharmacopœias are liable to serious adulteration, and there are very few cases on record during recent years where real fraudulent adulteration was involved. The numerous preparations used by druggists are mostly prepared in factories under competent and careful supervision, and the standards laid down in the British Pharmacopœia are, broadly speaking, carefully adhered to.

The article on Dietetics is fully in accord with modern knowledge, and is contributed jointly by W. O. Atwater, who is in charge of nutrition investigation in the United States Department of Agriculture, and R. D. Milner of the same department. They have compiled an interesting table based on modern researches, giving the amounts of nutrients and energy furnished for 1*s.* in food materials at ordinary prices.

Hygiene is defined in a short paragraph, the reader being very properly referred to the various branches of this big subject under the specific headings of dietetics, food, food preservation, adulteration, water, heating, ventilation, sewerage, bacteriology, housing, cremation, and so forth; while for legal enactments which concern the sanitary well-being of the community the reader is referred to the article on Public Health.

As an example of the care that has been taken to keep the scientific side of the Encyclopædia in touch with modern developments, we may refer to the series of monographs on drugs. They are not, as a rule, long dissertations, but they contain a *résumé* of the pharmacology of the particular drug under description. In the article on Ergot the fact that the extremely complex composition of this drug has been studied in great detail is cited, and the best modes of administration are given.

In the article on Cod liver Oil the researches on the composition of this complex substance are annotated, and it may be noted that the question of the value of active principles is ignored, and the correct statement is made that cod-liver oil has been proved to be more readily absorbed than any other oil. Further, we are glad to note that it is remarked that other oils or combinations of oils promise to give the same nutritive effects.

The various subjects, here only briefly alluded to, are brought well up to date, and considering how rapidly scientific methods advance and how quickly new materials come into existence the monographs on the whole show creditable performance upon the part of the contributors.

## MEDICINE AND THE LAW.

*Medical Examinations under the Workmen's Compensation Act.*

COMMENT was made in a leading article in THE LANCET of Sept. 17th, 1910, p. 899, upon the hearing of an application in the Westminster County Court to discontinue the payment of compensation made to a workman accidentally injured, on the ground that he had refused to submit himself to medical examination on behalf of his employers when asked to do so. Since then another case heard about the same time in the county court, and raising the same point upon similar facts, has been the subject of argument in the Court of Appeal, as well as a second in which a slight variation of the facts afforded the opportunity for further discussion of the principles involved. These two cases, besides appearing in the various law reports, will be found in close proximity to one another in "Butterworth's Compensation Cases" for the current year, or rather in the convenient "Quarterly Advance Sheets" in which these are issued before the year is completed. It will be seen that the case of Warby *v.* Plaistowe and Co. is precisely like the one to which our leading article referred, but it escaped comment at the time because his honour Judge Bray did not decide it at the time of the hearing of the argument before him, but waited till the long vacation before delivering in writing a judgment which, it may be mentioned, the Master of the Rolls described in the Appeal Court as an "admirable" one.

The applicant, Warby, to whom Messrs. Plaistowe and Co. were admittedly liable in respect of injuries received through an accident, was required by them to submit himself for examination by their medical man, Dr. R. J. Collie, either at his house in Porchester-terrace, Hyde Park, or at the workman's home in Eden-grove, Holloway. The workman, on the advice of his solicitors, refused to be examined except at their office, and in the presence of a member of their firm. The county court judge had to decide whether this constituted a refusal on the part of the workman to submit himself to a medical examination, or whether the conditions imposed were reasonable on account of the alleged conduct of Dr. Collie towards workmen on other similar occasions, the allegations made being to the effect that Dr. Collie treated injured workmen as if they were malingerers, and behaved towards them in a brutal manner. In his honour's judgment he assumed in the first place that the complaints against Dr. Collie were well founded, and decided that even if they were so the presence of his solicitor would not be a more efficient protection to the workman than that of his medical attendant, who could interfere, if necessary, during the examination, who would observe, far more intelligently than a solicitor, what was being done and the workman's conduct, and who could make a note of what was said and what passed. "I have assumed," Judge Bray said, "that the charge of brutality and the other allegations were well founded; I am satisfied, however, that they were not. There was no real foundation, in my opinion, for the charge of brutality." He referred to the case of Perry (reported as Terry) *v.* The London County Council (1910) in the *Times* of August 4th, and to Judge Woodfall's decision on that occasion (commented upon in the leading article referred to above), to the effect that the charges against Dr. Collie were without foundation, and he came to the conclusion that there was a refusal on the part of Warby to submit himself to examination and that his application to have his weekly payments continued must fail. It may be mentioned that early in his judgment Judge Bray stated that at the first hearing of the application before him in June he had suggested that Dr. Collie should examine the applicant at the court, that this had been done, and that Dr. Collie's report was that in his opinion the man was still totally incapacitated. In the Court of Appeal, after hearing argument on the part of the workman, and without calling upon counsel for the employers, the Master of the Rolls gave judgment dismissing the appeal and saying that "It is rather curious that in the case we have just decided (Harding *v.* The Royal Mail Steam Packet Company referred to below) I should have expressed the opinion that it cannot be too well known that a solicitor's office is not, in ordinary circumstances, a proper place at which to hold a medical examination of a workman, and I can only emphasise again what I there said on that point." His lordship went on to observe that in the case before the court there had been an attempt by the workman's solicitors to dictate to the employers where the man should be examined by their medical man, and after calling attention to the wording of the paragraph (14) in Schedule I. of the Act governing the matter he pointed out that the Act "gives the employer the sole right to select the medical man who shall examine the workman; it does not give the workman any right to impose conditions such as are claimed here."

In the other case to which reference has been made above, and to which the Master of the Rolls alluded in his judgment, that of Harding *v.* The Royal Mail Steam Packet Company, judgment was given on the same day as in Warby *v.* Plaistowe and Co. In it Dr. Collie was again

the medical man by whom the examination was to be made, but the condition which the workman wished to impose was different, in that his solicitors offered that he should attend for examination either at their office (Lime-street, E.) or at the surgery of the medical man who had attended him, but not at Dr. Collie's house in Porchester-terrace, although the employers' solicitors sent 10*s.* to cover the workman's fare to that address. His honour Judge Bacon held, on the facts, that the workman had not refused to submit himself to a medical examination, and the court dismissed the employers' appeal. The county court judge took no note of the evidence upon which his decision was based, which was referred to in the Court of Appeal as an unfortunate circumstance, but the principle laid down by the Master of the Rolls was that "as long as a man offers to submit himself to examination, and is not unreasonable in saying where it shall take place, he cannot be punished in the manner in which he would be if he acted otherwise." His lordship further said that it was a question of fact. "Was the refusal to go to the employers' doctor's surgery so unreasonable as to amount to a refusal to submit to examination, or to be obstruction?" His lordship could not say that it was, but it was a question for the learned county court judge. "Both parties took a wrong view." It will be seen from this that the Court of Appeal has not laid down that the examination must take place in the consulting-room of the medical man who is treating the workman if the latter so desires, but only that if the workman offers to submit himself to examination there, and refuses to attend at the house of the employer's medical man, he may be acting reasonably and may not be refusing to submit to examination. What is or is not reasonable in such circumstances is a question for the county court judge, which he will have to determine after considering the facts of the individual case if the question is brought before him.

Apart from the interest of these cases to medical men who may be called upon to make such examinations as Dr. Collie was asked to make, it is satisfactory to note that that gentleman's conduct has been completely vindicated by both Judge Woodfall and Judge Bray, in whose courts discussion took place with regard to it, and before whom the serious allegations referred to with regard to it were made.

*Bell* v. *Hunt: The Loss of a Sightless Eye.*

The principles under which compensation for incapacity is awarded under the Workmen's Compensation Act have now been laid down in so many decisions of the Court of Appeal and House of Lords that points practically unaffected by precedent do not often arise. One such appears, however, to have revealed itself in the claim of a workman named Bell, an edged-tool moulder, employed by Messrs. William Hunt and Sons, Limited, a Staffordshire firm. Bell was injured in the course of his work in September, 1910, by a piece of brick which struck his left eye, necessitating its removal. As a matter of fact, however, the eye thus removed had been already injured 15 years before and the sight of it had then been totally destroyed, although this defect had not prevented the man from obtaining employment under Messrs. Hunt, who had not been aware of it. When, however, after his eye had been removed Bell had applied to Messrs. Hunt to take him back they had declined to do so, and he had met with a similar refusal from several other firms, none of which would engage a man having only one eye. The county-court judge at West Bromwich had found (1) that Bell had not full capacity to do his work; and (2) that the accident which caused the blindness was not that of September, 1910, but the one which happened 15 years before, and on these findings he had made an award in favour of the employers from which the claimant appealed. The Master of the Rolls and Lord Justice Buckley agreed with the county-court judge, the former saying that disfigurement as distinct from incapacity was not, speaking generally, within the Act, although he suggested that it might be, for example, in such a case as that of a parlour-maid, whose face might be so scarred by an accidental burning as to prevent her from obtaining employment on the ground of her appearance. The incapacity to work in Bell's case, however, was in no sense due to the accident in September, 1910, which only made obvious the existence of prior incapacity, and the employers were not to be held liable because the workman could no longer conceal his defect. From the judgments of his colleagues Lord Justice Fletcher Moulton dissented, referring to the question of compensation as depending, as a general rule, upon whether the workman had sustained an injury which lessened his earning capacity. With regard to a point which had been raised, that the workman, if compensated, would be reaping advantage from his own wrong in concealing his defect, his lordship questioned whether it was the duty of a workman to reveal his defects when applying for employment. In his opinion, the man impliedly represented himself as skilled, but made no representation as to how he obtained or retained his skill. If an employer attached importance to unimpaired physical qualifications it was for him to make inquiry with regard to those of the workman whom he proposed to engage. Bell was justified in holding himself out when he obtained employment as capable of doing his work, and in his lordship's view the case ought to be remitted to the county-court judge to assess damages. In view of this division of opinion, which had as its result judgment for the respondents, the employers, owing to a majority of the court being in their favour, the case seems likely to be heard of again, and comment upon it, if any be needed, must be deferred until the House of Lords has had the opportunity of reviewing the effect of a combination of unusual circumstances not likely frequently to recur.

## BRITISH MEDICAL BENEVOLENT FUND.

AT the February meeting of the committee 27 cases were considered and grants amounting to £223 made to 19 of the applicants. Appended is an abstract of the cases relieved.

Daughter, aged 40, of late F.R.C.S. No income; delicate health and dependent on mother, whose income is only 10*s.* a week. Relieved 11 times, £98. Voted £12.

M.B., C.M. Edin., aged 61. No income and incapacitated by hemiplegia; four children, all dependent. Voted £12.

Widow, aged 52, of L.F.P.S. Glasg. No income; takes in boarders and receives a little help from a daughter earning 14*s.* a week; health very delicate. Relieved seven times, £70. Voted £12.

Widow, aged 37, of L.R.C.P., L.R.C.S. Edin. Unprovided for at husband's death about ten years ago and has supported herself by nursing; two children. Now asks for a little help towards the school fees of the elder daughter, aged 15. Voted £10.

Widow, aged 62, of M.D. Lond. At husband's death 12 years ago took a boarding house, but has been obliged to exhaust all her capital in order to meet expenses. Voted £12.

Daughters, aged 70 and 63, of late M.R.C.S., L.S.A. Were comfortably provided for at father's death 20 years ago, but made very unfortunate investments and are now practically penniless. Voted £18.

Widow, aged 65, of M.R.C.S. Husband's means were exhausted by a long illness, ending in death a few months ago, and applicant has chronic glaucoma. No children. Voted £12.

Daughter, aged 62, of late M.R.C.S., L.S.A. Since father's death in 1903 has held situations as cook-housekeeper, &c., but is now unable to obtain employment. Voted £12.

M.R.C.S., aged 64. Has completely broken down in health and is practically penniless. Voted £12.

Daughter, aged 49, of late M.R.C.S. Quite unprovided for at father's death and has maintained herself for nearly 20 years, but is now in a delicate state of health and can only undertake occasional and light work. Voted £12.

M.R.C.S., L.R.C.P., aged 51. Is in pecuniary distress through no fault of his own and asks for a little help towards unavoidable expenses before going abroad. Voted £5.

Widow, aged 49, of M.B. Durh. At husband's death 20 years ago started a nursing home and supported herself and a widowed mother, but is now broken down in health and requires a rest. Two children, both delicate and barely self-supporting. Relieved three times, £29. Voted £12.

Widow, aged 66, of L.R.C.P. Edin. Has given music lessons and taken lodgers, but is now in bad health and dependent on a daughter earning £1 a week. Relieved six times, £60. Voted £12.

Widow, aged 60, of M.D. Glasg. No income and dependent on a son who can ill afford to help. Relieved once, £12. Voted £12.

Daughter, aged 56, of late M.R.C.S. Endeavours to support herself by letting lodgings but finds it impossible to meet unavoidable expenses. Relieved four times, £55. Voted £10.

Widow, aged 69, of L.F.P.S. Glasg. Husband's means were exhausted by a long illness which preceded his death and applicant endeavours to maintain herself by taking boarders; health indifferent. Relieved three times, £22. Voted £12.

Daughter, aged 49, of late M.R.C.S. No income; health too delicate to admit of employment and dependent on a brother-in-law whose earnings are extremely small. Relieved twice, £24. Voted £12.

Widow, aged 65, of L.R.C.P., L.R.C.S. Edin. Is quite penniless and dependent on a married son earning £1 a week. Relieved 12 times, £129. Voted £12.

Widow, aged 45, of L.R.C.P., L.R.C.S. Edin. No income and children unable to help; is incapacitated by a chronic complaint and practically dependent on help given by this fund and another society. Relieved 15 times, £172. Voted £12.

Contributions should be sent to the honorary treasurer, Dr. Samuel West, 15, Wimpole-street, London, W.

# Public Health.

## ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

*Chelmsford Rural District.*—Dr. J. C. Thresh, who takes much interest in the question of housing in rural districts, thinks that the powers conferred by Sections 16 and 17 of the Housing and Town Planning Act, 1909, are not likely to prove of much service at present since the council here in question is reluctant to accept the responsibility for closing orders. As regards the power of appeal to the Local Government Board which is given to owners Dr. Thresh regards it as more disconcerting than an appeal to the magistrates or court of sessions would be. He reports that more cottages are required in several of the parishes, but the council is not inclined to take action in face of the fact that if the farmers provided proper accommodation for their labourers there would be no necessity for action on the part of the council, which objects, and Dr. Thresh thinks naturally, to subsidise the land by providing cheap cottages for the labourers employed thereon. Another objection in his opinion is the unfairness of saddling any parish or area with rates in order that a few of the inhabitants may occupy cottages at a low rental. The way out of the difficulty is, Dr. Thresh thinks, for the council to provide where required a few cottages with three bedrooms and to let them at a rent which will involve no loss to the ratepayers. This suggestion seems to accept it as established that the labourers could and would pay the rent necessary to prevent loss; in other words, it raises a large and somewhat difficult problem. But there can be no doubt as to the very great difficulty of adequate housing in rural districts, and Dr. Thresh refers to an illustrative case which occurred at Ingatestone, where there were several cottages belonging to three different owners which were considered unfit for habitation. Two of the owners offered to close their cottages at once if the council would serve closing orders, an action which would have involved turning eight families into the street. The owners refused to make any structural alteration and presumably the council refused to issue the closing orders and the cottages remain occupied. There seems, however, prospect of a solution so far as a part of Ingatestone is concerned owing to the offer of a local builder to erect as many cottages as would be required, not exceeding 50, provided that the council would offer facilities for drainage and would carry the water main to the site, conditions to which the council agreed subject to the Local Government Board sanctioning a loan for sewer extension. But here again, to some extent at least, there comes in the principle of the ratepayers helping the farmer to house his labourers, inasmuch as it does away with the expense of sinking wells and cesspools. Dr. Thresh furnishes in another part of his report an example of the facility with which diseased meat may find its way into butchers' shops. At two slaughter-houses in the district there is a suspicion that unsound animals are slaughtered, and in one of these places the carcass of a cow which had suffered from a disease rendering it unfit for human consumption was found. It was alleged that the cow had been fetched from a farm and slaughtered for the sale of its hide, and the flesh was, the butcher stated, being sent to the kennels. The clerk to the district council was consulted as regards seizure, but in his opinion it was not a legal offence to have either a diseased animal or a diseased carcass in a slaughter-house, and if it was diseased or unfit for human food there should be evidence that it was intended for human consumption, otherwise the owner might claim damages from the council. It is difficult to find fault with this reasoning, but clearly the law requires amendment to cover obvious risks such as this, more especially as in a very large number of sanitary districts, whether they be rural or small urban districts, meat inspection is not carried out, largely because neither the medical officers of health nor the sanitary inspectors have had any special training in meat inspection, and the district councils do not offer them any encouragement or facilities for acquiring such experience. Gradually we are moving forward, but at the present rate the current century will be far advanced before the inspection referred to is of much value.

*Woking Urban District.*—Dr. R. W. C. Pierce, reporting upon the housing of the working-classes in this district, states that the sanitary committee went thoroughly into the subject during the past year, and that their method of investigation consisted in taking the evidence of the officials as well as of several members of the public who had manifested an interest in the subject. Dr. Pierce, as the result of observations made, concludes that there are many families in the district who cannot, with due regard to the necessary expenditure on food and clothing, pay the rents prevailing in the district, and consequently they are obliged to share a house with another family, an arrangement which leads to overcrowding and other evils. The average rental (inclusive of rates) for a cottage with three bedrooms is between 7*s.* 6*d.* and 8*s.* 6*d.* a week, a rent which is obviously beyond the means of many of the labouring classes. Dr. Pierce regards it as an urgent necessity that the disproportion between the income and rent should be diminished either by providing cottages at a lower rental or by giving the labouring classes more constant and remunerative work, or by a combination of both methods. It seems that a row of cottages which was not being properly looked after by the owners was taken over by an association who let the houses to struggling and deserving families with very satisfactory results, lady visitors keeping a strict supervision over the cottages. The weekly rental of these eight cottages, which were taken over on lease, was formerly 7*s.*, but it has now been reduced to 6*s.* 6*d.*, the tenants earning from 16*s.* to 20*s.* per week. Lodgers are not allowed to be taken without consent, and a return of 3 per cent. only is expected from the association. Dr. Pierce suggests that other similar blocks of dwellings should be taken over by the council, and he thinks that self-contained cottage flats will meet a part of the existing need for cheaper dwellings. Gipsy encampments appear to cause some trouble in this district from the circumstance that some of them are pitched in low-lying and damp situations where slop and waste water cannot be properly disposed of. Moreover, the condition of the tents and vans is not satisfactory.

## REPORTS OF SCHOOL MEDICAL OFFICERS.

*The County of Berkshire.*—Dr. Gerard C. Taylor, the school medical officer and county medical officer of health, reports that during the year 1910 there were 58 schools or departments closed owing to infectious sickness, 17 of these being closed by the medical officer of health with the approval of the school medical officer, and 41 by the local education authorities or school managers acting on the advice of the school medical officer. During the year material improvement was made in the lighting, ventilation, and heating of several of the schools. In the cloakrooms the indiscriminate use of the pegs is prevented by each child being required to use his or her duly numbered peg. As regards the playgrounds tar-paving is not made as much use of as could be desired. The total population of this administrative area is estimated at about 142,556, and the number of children on the rolls of the elementary schools is about 24,271, no children under 5 years of age being admitted. The actual medical inspection has been carried out by two assistant school medical officers, but both these resigned their posts during the year 1910, one to become county medical officer and school medical officer of Rutland, and the other to join the staff of the London Education Committee. In two instances gratuitous dental treatment has been provided, in one case the cost being borne by one of the managers, and in the other the managers have accepted the offer of a dental surgeon to treat the children gratuitously when sent to him by the parents, and the committee have placed a room in the school at his disposal. In another instance a nursing association, acting as a care committee for two schools in this area, have arranged with a dentist to inspect the children gratuitously and to undertake any necessary treatment for a small fee, to be paid by the parent. This local scheme will probably include the sale of toothbrushes at a small cost.

# VITAL STATISTICS.

## HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns 7963 births and 5052 deaths were registered during the week ending March 18th. The annual rate of mortality in these towns, which had steadily declined in the five preceding weeks from 17·6

to 14·9 per 1000, rose again to 15·4 in the week under notice. During the first 11 weeks of the current quarter the death-rate in these towns averaged 15·9 per 1000, and the mean recorded rate in London during the same period was also equal to 15·9. The annual death-rates during last week ranged from 4·9 in Handsworth, 5·3 in King's Norton, 7·6 in Wallasey, and 8·3 in Northampton, to 21·9 in Sheffield, 22·5 in Middlesbrough, 22·7 in Plymouth, and 23·3 in Coventry. The 5052 deaths from all causes in the 77 towns showed an increase of 141 upon the number returned in the previous week, and included 695 which were referred to the principal epidemic diseases, against numbers increasing from 477 to 702 in the five preceding weeks; of these 695 deaths, 460 resulted from measles, 109 from whooping-cough, 44 from diphtheria, 42 from infantile diarrhœa, 22 from scarlet fever, 17 from enteric fever, and 1 from small-pox. The annual death-rate in the 77 towns from these epidemic diseases averaged 2·1 per 1000. The fatal cases of measles, which had steadily increased from 160 to 474 in the first ten weeks of the current quarter, declined last week to 460; the highest annual death-rates from this disease among the 77 towns last week were 3·8 in Coventry, 4·1 in Plymouth, 5·4 in Devonport, 5·6 in Wigan, and 8·0 in Sheffield. The deaths from whooping-cough, which had been 108 and 80 in the two previous weeks, rose again to 109 last week; they caused the highest rates last week, 1·7 in Wigan, 1·8 in Aston Manor, and 1·9 in Coventry and in West Hartlepool. The 44 deaths from diphtheria showed a further decline of 12 from the numbers in recent weeks; they included 13 in London and its suburban districts, 4 in Leeds, and 3 both in Bristol and in Sheffield. The 42 deaths of infants under 2 years of age attributed to diarrhœa, showed a further decline from the numbers in recent weeks, and were fewer than in any previous week of this year. The 22 fatal cases of scarlet fever also showed a further decline from the numbers in recent weeks; 4 were recorded in London and 2 each in Liverpool, Stoke-on-Trent, and Bury. The deaths referred to enteric fever, which had been 15 and 13 in the two previous weeks, rose to 17 last week, of which 3 occurred in Manchester, 3 in Leeds, and 2 both in London and in Portsmouth. The fatal case of small-pox occurred in London, and was admitted to hospital from Poplar. The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospital, which had declined in the four preceding weeks from 1276 to 1166, had further fallen to 1121 on Saturday last; 146 new cases of this disease were admitted to these hospitals during last week, against 138, 129, and 120 in the three preceding weeks. These metropolitan hospitals also contained on Saturday last 920 cases of diphtheria, 822 of measles, 256 of whooping-cough, 32 of enteric fever, and 38 of small-pox. The 1419 deaths from all causes in London last week, an increase of 28 upon the number in the previous week, included 284 which were referred to diseases of the respiratory system, against numbers ranging from 421 to 318 in the four preceding weeks; 7 deaths were also referred to influenza. In the 77 towns 156 deaths from different forms of violence were registered during last week, against 173, 153, and 142 in the three preceding weeks; and 377 inquest cases were recorded. The causes of 46, or 0·9 per cent., of the deaths registered during the week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, Bristol, Bradford, Newcastle-on-Tyne, Nottingham, Leicester, Salford, and in 47 other smaller towns; the 46 uncertified causes of death in the 77 towns last week included 9 in Birmingham, 4 in Stoke-on-Trent, and 3 each in Liverpool, Sheffield, and Preston.

### HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 907 births and 617 deaths were registered during the week ending March 18th. The annual rate of mortality in these towns, which had steadily declined in the five preceding weeks from 19·8 to 15·9 per 1000, rose again to 16·8 in the week under notice. During the first 11 weeks of the current quarter the death-rate in these towns averaged 17·0 per 1000, and exceeded by 1·1 the mean rate during the same period in the 77 English towns. The annual death-rate last week in the eight Scotch towns ranged from 14·3 and 14·6 in Leith and Aberdeen to 20·1 in Dundee and 20·8 in Paisley. The 617 deaths from all causes in the eight towns last week showed an increase of 34 upon the number returned in the previous week, and included 66 which were referred to the principal epidemic diseases, against 76, 57, and 60 in the three preceding weeks; these 66 deaths were equal to an annual rate of 1·8 per 1000, which was 0·3 below the rate from the same diseases in the 77 English towns; the highest rates from these diseases in the Scotch towns last week were 3·3 in Paisley and 4·2 in Leith. Of these 66 deaths from epidemic diseases last week in the eight towns 36 resulted from whooping-cough, 11 from diarrhœa, 9 from diphtheria, 5 from scarlet fever, 4 from measles, and 1 from enteric fever, but not one from small-pox. The fatal cases of whooping-cough, which had been 32 and 36 in the two previous weeks, were again 36 last week, and included 15 in Glasgow, 5 each in Edinburgh, Paisley, and Leith, and 4 in Dundee. The 11 deaths attributed to diarrhœa (of which 10 were of infants under two years of age), exceeded the number in the previous week by 4, and included 5 both in Glasgow and in Dundee. The deaths referred to diphtheria, which had been 5 in each of the two previous weeks, rose to 9 last week; 4 occurred in Edinburgh and 3 in Glasgow. Of the 5 fatal cases of scarlet fever, 2 were recorded in Glasgow; and the 4 deaths from measles included 2 both in Glasgow and in Edinburgh. The death resulting from enteric fever was registered in Leith. The deaths referred to diseases of the respiratory system in the eight towns, which had declined in the four preceding weeks from 181 to 108, were 109 in the week under notice. The 18 deaths attributed to different forms of violence were within 2 of the number in the previous week; and 180, or 29 per cent., of the 617 deaths from all causes occurred in public institutions. The causes of 21, or 3·4 per cent., of the deaths registered in the eight towns during the week were not certified or not stated; in the 77 English towns last week the proportion of uncertified causes of death did not exceed 0·9 per cent.

### HEALTH OF IRISH TOWNS.

In the 22 town districts of Ireland, having an estimated population of 1,163,596 persons, 612 births and 389 deaths were registered during the week ending March 18th. The annual rate of mortality in these towns, which had steadily declined in the five preceding weeks from 24·1 to 19·3 per 1000, further fell to 17·4 in the week under notice. During the first 11 weeks of the current quarter the annual death-rate in these 22 towns averaged 20·4 per 1000; the rate during the same period did not exceed 15·9 in the 77 English towns, and 17·0 in the eight Scotch towns. The annual death-rate during last week was equal to 20·8 in Dublin, 15·4 in Belfast, 16·4 in Cork, 10·7 in Londonderry, 15·0 in Limerick, and 15·6 in Waterford; in the 16 smallest of the Irish towns the mean annual death-rate last week was equal to 17·2 per 1000. The 389 deaths from all causes in the 22 towns last week showed a further decline of 42 from the numbers returned in recent weeks and included 21 which were referred to the principal epidemic diseases, against 41, 25, and 26 in the three preceding weeks; these 21 deaths were equal to an annual rate of 0·9 per 1000, which was 1·2 below the mean rate from the same diseases in the 77 English towns. Of these 21 deaths in the Irish towns from the principal epidemic diseases, 8 resulted from measles, 6 from diarrhœa, 5 from whooping-cough, and 1 each from scarlet fever and enteric fever, but not one either from small-pox or diphtheria. The 8 fatal cases of measles, of which 7 occurred in Dublin and 1 in Drogheda, showed an increase of one on the number in the previous week. The 5 deaths from whooping-cough showed a further considerable decline from the numbers in recent weeks; they included 4 in Dublin and 1 in Belfast. Five of the 6 deaths attributed to diarrhœa occurred in Dublin. The death referred to enteric fever was recorded in Dublin, and the fatal case of scarlet fever occurred in Belfast. The deaths in the 22 towns referred to diseases of the respiratory system, which had declined in the five preceding weeks from 141 to 100, further fell last week to 90. Of the 389 deaths from all causes last week, 105, or 27 per cent., were recorded in public institutions. The causes of 13, or 3·3 per cent.,

* Including membranous croup. † The death-rates are corrected for variations in sex- and age-constitution of the populations of the several boroughs, the population of England and Wales being taken as the standard. ‡ Deaths from "typhus fever" and "other continued fevers" are not now distinguished in the Registrar-General's weekly returns; these two columns are therefore omitted from the Table.

of the deaths in the 22 towns last week were not certified either by a registered medical practitioner or by a coroner after inquest; the proportion of uncertified causes of death last week did not exceed 0·9 per cent. in the 77 English towns, and was 3·4 per cent. in the eight principal Scotch towns.

### VITAL STATISTICS OF LONDON DURING FEBRUARY, 1911.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 4·1 per 1000 of the population, provisionally estimated at 4,912,504 persons in the middle of this year. In the three preceding months the rates were 5·0, 4·3, and 4·1 per 1000 respectively. The lowest rates last month were recorded in Westminster, St. Marylebone, St. Pancras, Stoke Newington, Holborn, the City of London, Camberwell, and Greenwich; and the highest rates in Fulham, Stepney, Bermondsey, Battersea, Wandsworth, and Woolwich. Twenty-eight cases of small-pox were notified last month, 26 belonging to Stepney, one to the City of Westminster, and one to Poplar. The prevalence of scarlet fever showed no variation from that recorded in the preceding month; among the several metropolitan boroughs the greatest proportional prevalence of this disease was recorded in Chelsea, the City of Westminster, Bermondsey, Battersea, Wandsworth, and Woolwich. The Metropolitan Asylums Hospitals contained 1224 scarlet fever patients at the end of last month, against 1727, 1574, and 1280 at the end of the three preceding months; the weekly admissions averaged 142, against 183, 155, and 130 in the three preceding months. Diphtheria was rather more prevalent than it had been in other recent months; this disease showed the greatest proportional prevalence in Fulham, Hampstead, Stepney, Bermondsey, Battersea, and Lewisham. The number of diphtheria patients remaining under treatment in the Metropolitan Asylums Hospitals at the end of last month was 902, against 866, 827, and 842 at the end of the three preceding months; the weekly admissions averaged 120 last month, against 106, 95, and 107 in the three preceding months. The prevalence of enteric showed a marked decline; among the several metropolitan boroughs this disease was proportionally most prevalent in Paddington, Hampstead, Finsbury, Poplar, and Greenwich. There were 41 enteric fever patients under treatment in the Metropolitan Asylums Hospitals at the end of last month, against 88 and 68 at the end of the two preceding months; the weekly admissions averaged 7, against 16, 11, and 7 in the three preceding months. Erysipelas was proportionally most prevalent in Hackney, Finsbury, Shoreditch, Bethnal Green, Stepney, and Southwark. The 21 cases of puerperal fever notified during the month included 5 in Woolwich and 3 in Lewisham. Of the 10 cases notified as cerebro-spinal meningitis, 2 belonged to Lambeth.

The mortality statistics in the table relate to the deaths of persons actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the several boroughs in which the deceased persons had previously resided; the death-rates from all causes are further corrected for variations in the sex and age constitution of the population of the several boroughs. During the four weeks ending Feb. 25th the deaths of 6299 London residents were registered, equal to a corrected annual death-rate of 17·6 per 1000, against 15·8 and 16·5 in the two preceding months. The death-rates last month ranged from 10·2 in Hampstead, 12·4 in Greenwich, 13·0 in Stoke Newington, 13·1 in Lewisham, 14·8 in Fulham, and 15·3 in Woolwich, to 20·9 in Bermondsey, 21·0 in Bethnal Green, 21·1 in Finsbury and in Poplar, 21·2 in St. Marylebone, 24·3 in Shoreditch, and 27·6 in the City of London. The 6299 deaths from all causes included 416 which were referred to measles, 14 to scarlet fever, 54 to diphtheria, 136 to whooping-cough, 7 to enteric fever, and 70 (among children under two years of age) to diarrhœa and enteritis. No death from any of these diseases was recorded in the City of London; among the metropolitan boroughs they caused the lowest death-rates in Paddington, the City of Westminster, Hampstead, Greenwich, and Woolwich; and the highest rates in Kensington, Finsbury, Shoreditch, Bethnal Green, Poplar, and Battersea. The 416 deaths from measles were 268 in excess of the corrected average number in the corresponding period of the five preceding years; the greatest proportional mortality from measles last month was recorded in Kensington, St. Marylebone, Finsbury, Shoreditch, Bethnal Green, Stepney, Poplar, and Battersea. The 14 fatal cases of scarlet fever were 22 below the corrected average number, and included 3 in Bermondsey and 2 each in Islington, Wandsworth, and Deptford. The 54 deaths from diphtheria were 12 fewer than the corrected average number; this disease was proportionally most fatal in Kensington, Hammersmith, Finsbury, Poplar, Bethnal Green, and Wandsworth. The 136 fatal cases of whooping-cough showed a decline of 23 from the corrected average number; the greatest proportional mortality from this disease was recorded in Hammersmith, Hackney, Shoreditch, Bethnal Green, Southwark, and Bermondsey. The 7 deaths from enteric fever were 5 below the corrected average number; these 7 deaths belonged respectively to the City of Westminster, St. Marylebone, Hampstead, Islington, Poplar, Southwark, and Lewisham. The 70 deaths from diarrhœa and enteritis among children under two years of age included 10 in Stepney, 6 in Hammersmith, 5 in Battersea, 4 in Islington, and 4 in Wandsworth. In conclusion, it may be stated that the aggregate mortality in London last month from the principal infectious diseases (excluding diarrhœa) was nearly 50 per cent. above the average.

## THE SERVICES.

### ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet-Surgeon: H. W. Gordon-Green to the *Hampshire*, on recommissioning. Staff-Surgeons: W. R. Trythall to the *Aboukir*, on recommissioning; and A. Davidson to the *President*, additional, for three months' hospital course at the West London Hospital. Surgeons: A. S. Paterson to the *Hearty*; E. L. Markham to the *Triton*; H. B. German to the *Jupiter*, additional; E. B. Kenny to the *King Alfred*; H. Burns to the *Halcyon*, additional, for the *Spanker*, on recommissioning; A. Fairley to the *Aboukir*, on recommissioning; A. T. Rivers to the *Africa*; A. L. Robinson to the *Victory*, additional, for disposal on the *Dreadnought* paying off; and L. C. R. Robinson to the *President*, additional, for three months' hospital course at the Dreadnought Seamen's Hospital.

### ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel C. Birt, Officer Commanding No. 14 Company, Royal Army Medical Corps and in charge of the Royal Infirmary at Dublin, has been selected for the higher rate of pay under Article 317 of the Royal Warrant, vice Lieutenant-Colonel J. M. Reid retired. Lieutenant-Colonel H. D. Rowan has been transferred from the Aldershot to the Southern Command and appointed in Charge of the Military Hospital at Tidworth Park, Salisbury Plain. Lieutenant-Colonel T. G. Lavie has been transferred from Newbridge to Queenstown. Lieutenant-Colonel S. Hickson, from Potchefstroom, has taken up duty at Wynberg. Lieutenant-Colonel G. E. Hale, D.S.O., has taken over command of the Station Hospital at Mhow. An exchange in the roster for service abroad has been approved by the War Office between Lieutenant-Colonel W. W. Pike, D.S.O., and Lieutenant-Colonel C. R. Tyrrell. Major H. A. Hinge, on completion of a tour of service in India, has been posted to the London District and appointed to the Recruiting Medical Staff. Major A. H. Morris has vacated his appointment in the Scottish Command and embarked for Malta to take over duty as Specialist Sanitary Officer. Major S. W. Sweetnam, commanding the Military Hospital at Kirkee, has been granted six months' leave of absence. Major J. C. B. Statham, on return from a tour of service in South Africa, has been appointed Clinical Pathologist to Queen Alexandra's Military Hospital at Grosvenor-road. Approval has been given to the grant of pay at higher rate under the provision of Article 317 of the Royal Warrant to the following majors with 20 years' service and qualified for promotion to the rank of Lieutenant-Colonel, viz.: E. E. Powell, E. McK. Williams, J. C. Connor, F. W.

Hardy, W. A. S. J. Graham, D. D. Shanahan, C. W. H. Whitestone, A. Pearse, and C. Dalton. Major C. A. Young has arrived home from Mauritius. Major W. J. Taylor has embarked for Sierra Leone. Major A. W. Bewley, commanding the Station Hospital at Landour, has joined for duty at Meerut. Captain J. E. Powell, Captain R. K. White, Captain E. B. Booth, and Captain W. G. Maydon have arrived home tour-expired from India. Captain G. F. Rugg has taken up duty as Specialist in Advanced Operative Surgery to the Fourth (Quetta) Division. Captain C. R. M. Morris, from Sialkot, has been granted six months' general leave of absence. The appointment of Captain E. Bennett as Adjutant to the Royal Army Medical Corps School of Instruction, North Midland Division, has been extended to Oct. 31st next. Captain H. O. M. Beadnell, on sick leave from India, has been reverted to the home establishment, tour-expired. Captain G. J. Houghton has embarked for a tour of service on the West Coast of Africa. Captain H. Simson, Specialist in the Prevention of Disease, has been transferred from Ahmednagar to Poona. Captain E. J. Kavanagh, from Ranikhet, has taken up duty at Delhi. Captain R. C. Hallowes, from Cairo, has been appointed for duty at Dundalk. Captain E. S. Worthington, M.V.O., Specialist in Advanced Operative Surgery, has been posted to the London District. Lieutenant G. F. Dawson has been transferred from Chakrata to Meerut Cantonment. Lieutenant T. B. Nicholls, from Tidworth Park, has taken up duty at the Military Hospital, Cairo. Lieutenant R. C. G. M. Kinkead, from Buttevant, has been appointed to the Cork District. Lieutenant J. C. L. Hingston has been posted to Madras.

INDIAN MEDICAL SERVICE.

The King has approved of the following promotions of officers of the Indian Medical Service:—Majors to be Lieutenant-Colonels: James Muir Crawford, Bawa Jiwan Singh, Ernest Gerald Robert Whitcombe, Charles Henry James, Frederick O'Kinealy, and Arthur William Treminhere Buist (dated Jan. 31st, 1911). Captains to be Majors: Corrie Hudson, D.S.O., Charles Frederick Weinman, Hamilton Maxwell Cruddas, George King, George Patrick Thomson Groube, Pandit Piaraylal Atal, William MacMullen Pearson, and David Claude Kemp (dated Jan. 28th, 1911).

Surgeon-General C. P. Lukis, C.S.I., Director-General of the Indian Medical Service, has been granted a good service pension, vice Surgeon-General Sir Gerald Bomford, K.C.I.E. Lieutenant-Colonel J. T. Calvert has taken over duty as Principal of the Medical College, Calcutta, during the absence on leave of Lieutenant-Colonel F. J. Drury. Lieutenant-Colonel C. F. Willis has been granted seven months' leave of absence home from India. Lieutenant-Colonel H. Handley, civil surgeon, on completion of special duty at the headquarters of the Second (Rawalpindi) Division, has been appointed Civil Surgeon of Lahore in succession to Lieutenant-Colonel D. T. Lane, transferred. Lieutenant-Colonel W. A. Sykes, Bengal, has arrived home on leave. Lieutenant-Colonel R. Robertson has joined at Madras. The services of Lieutenant-Colonel R. B. Roe, civil surgeon and superintendent of the Lunatic Asylum at Nagpur, have been placed at the disposal of the Army Department. Lieutenant-Colonel J. W. Rodgers, in medical charge of the 52nd Sikhs (Frontier Force), has been granted four and a half months' leave of absence from India. Major E. E. Waters has been appointed to officiate as Professor of Materia Medica and Second Physician at the College Hospital, Calcutta. Major H. Innes, civil surgeon at Mymensingh, has been appointed Civil Surgeon at Shillong, in succession to Major E. C. Macleod, appointed additional Civil Surgeon at Dacca. Major C. Donovan has been granted five months' extension of his leave by the Secretary of State, on medical certificate. Major E. D. W. Greig has been appointed to officiate as Director of the Central Research Institute at Kasauli during the absence on leave of Lieutenant-Colonel Sir David Semple, R.A.M.C. Major C. Duer has been confirmed in the appointment of Civil Surgeon of Simla (West). Major J. L. Macrae, civil surgeon of Coorg, has been granted privilege leave combined with furlough, for eight months. Major H. Boulton has been granted one month's extension of his leave of absence from India. Captain S. T. Crump, civil surgeon of Loimwe, has been appointed Resident Medical Officer at the General Hospital, Rangoon. Captain W. G. Hamilton has been appointed to officiate as Superintendent of the Presidency Jail at Calcutta during the absence on leave of Major J. Mulvany. Captain D. H. F. Cowin has taken over charge of the Dera Ghazi Khan District Jail from Captain A. K. Lauddie. Captain M. Foster Reaney has been appointed to officiate as Civil Surgeon of Nagpur. Lieutenant A. Mac D. Dick has been appointed Specialist in Advanced Operative Surgery to the Burma Division. Lieutenant R. B. Lloyd, officiating as medical officer in charge of the 58th Vaughan's Rifles, has been transferred to the 31st Duke of Connaught's Own Lancers at Kohat and attached for duty. Lieutenant B. Gale has been appointed as Specialist in Radiography and Electrical Science to the First (Peshawar) Division.

SPECIAL RESERVE OF OFFICERS.

*Royal Army Medical Corps.*

Sydney James Higgins to be Lieutenant (on probation) (dated Feb. 15th, 1911).

TERRITORIAL FORCE.

*Royal Army Medical Corps.*

3rd Northern General Hospital, Royal Army Medical Corps: James Martin Beattie to be Major (dated Jan. 2nd, 1911).

*Attached to Units other than Medical Units.*—Captain Cecil A. Corke resigns his commission, and is granted permission to retain his rank and to wear the prescribed uniform (dated March 18th, 1911). Lieutenant Thomas Price Thomas to be Captain (dated Feb. 16th, 1911). Captain John G. Ronald resigns his commission (dated March 22nd, 1911).

*For Attachment to Units other than Medical Units.*—Robert Henry to be Lieutenant (dated Jan. 9th, 1911).

ROYAL ARMY MEDICAL CORPS EXAMINATION.

A competition for not less than 20 commissions in the Royal Army Medical Corps will be held on July 26th next and following days. Applications to compete should be made to the Secretary, War Office, not later than July 17th.

# Correspondence.

"Audi alteram partem."

## CHARLES BELL AND THE MOTOR AND SENSORY FUNCTIONS OF SPINAL NERVES.

*To the Editor of* THE LANCET.

SIR,—Professor A. Keith (THE LANCET, March 18th) bases his opinions principally upon: (1) Sir Charles Bell's letters published by Lady Bell in 1870 (Messrs. Murray); and (2) Alexander Shaw's "Narrative of the Discoveries of Sir Charles Bell in the Nervous System" (1839). I am, of course, well acquainted with both these publications, and while fully recognising their value as documents to character, I cannot accept them as scientific evidence relating to the physiological events of 1821–22. They, among other publications, were present to my mind when I stated that no evidence subsequent to 1822 can be accepted as "authoritative," and I hope that Professor Keith will believe that in my desire to limit the field of discussion to the scientific publications of the time I was doing my best—with due justice to "my countryman" as well as to Magendie—to keep the name of Sir Charles Bell as free as possible from the unfortunate polemics that arose after 1822, chiefly through the devoted advocacy of the two Shaws. And, with considerable knowledge of the facts, I deliberately repeat the statement that no publication subsequent to 1822 is to be regarded as authoritative; the case between Bell and Magendie as regards the nerve-roots is limited to the publications of 1811 and 1822. The tedious "narrative" promulgated by the younger Shaw in 1839, and adopted by Professor Keith as authoritative in 1911, is not entitled to rank as evidence. Nevertheless, at this stage I am afraid I cannot avoid dealing with two points raised in this connexion by Professor Keith—viz., (1) the incident of the prize medal in connexion with Shaw's visit to Paris in 1821; and (2) the experiment of the dead rabbit.

Shaw's visit to Paris in 1821 is mentioned by Shaw himself in the footnotes of pages 84 and 89 of vol. ii. (1822) of Magendie's *Journal de Physiologie;* the facts about the prize-medal are as follows. Magendie in 1821—38 years of age, at the zenith of his extraordinary powers, the undisputed master of his science in Paris and throughout the continent, member of nearly every important scientific body in Europe—gave a full account of Bell's 1821 paper on the nerves of the face, as he did of any paper that he deemed to be of value, and shortly afterwards invited Bell to demonstrate his principal experiments as a preliminary to making a report concerning the adjudication of a prize—as was then and still is the custom of the Académie des Sciences. Mr. John Shaw, who was at that time Bell's demonstrator at the Windmill-street School of Anatomy, went over to Paris, and was only partially successful in his demonstration—for various reasons of which he himself gives explanations—and the medal was not awarded to Bell.

The experiment of the dead rabbit—which even now and with careful explanation is an excellent class demonstration—is first described by Bell in the preface to his "Exposition of the Nervous System" of 1824, at p. 29.[1] Professor Keith, after quoting the more popular description of the experiment given in Bell's "Letters," at p. 171, goes on to say that:—

> No statement could be clearer as to the function of the roots. At this early date (March 12th, 1810) Bell recognised that the spinal roots were different in function and that the anterior root was "*sensible*" (*motor* in modern terminology), and the posterior "*insensible*," or sensory ..... &c.

Slightly simplified, does this not amount to saying that no statement could be clearer as to the function of the roots, because Bell recognised that the anterior root was "*sensible*"—by which, of course, he meant motor—and the posterior "*insensible*"—by which, of course, he meant sensory? Anyhow, could not the statement have been clearer?

Professor Keith also directs attention to the related but collateral case of the fifth nerve. That is a different and more complicated matter, involving many other publications besides those of Bell and of Magendie. Bell's contribution to the advancement of our knowledge of the fifth (and seventh) nerves is contained in the two papers of 1821 and 1822 in the Philosophical Transactions of the Royal Society referred to in the footnote of my letter of March 4th. I do not wish to follow Professor Keith into this complicated matter until the simpler matter of the nerve roots has been disposed of, beyond stating briefly: 1. That anatomically the nature of the fifth pair and its similarity to a spinal nerve were clearly described in anatomical treatises long before 1821, as is indicated by the names applied to it—viz., *portio major quinti paris vel nervus trifacialis et portio minor quinti paris vel nervus masticatorius.* 2. The physiological point that in 1821 Bell attributed to the entire fifth pair both motor and sensory functions, and not, as Professor Keith represents, sensory function to the portio major (trifacialis), motor function to the portio minor (masticatorius).

Dr. Leonard Guthrie's references to Magendie are quite correct, so also is his appreciation of the generous manner in which Magendie met the claim to Bell's priority preferred through the elder Shaw. Magendie, as is evident in the first two volumes of his *Journal de Physiologie*, treated Bell (*J. de P.*, I., 384, and II., 66, 363) with the utmost consideration as a man of science on the same footing as Broughton (I., 120) and Rolando (III., 95) and Brodie (III., 93) and Shaw (II., 77) and Mayo (III., 345) and Christison (III., 274), and whose discoveries, as described by themselves, he translated and published in the *Journal de Physiologie*, and as a matter of fact it is clear that Magendie gave Bell more than his due credit in conceding to him the priority of having divided the separate roots as a physiological operation. The only other mention by Bell of anything resembling a section of nerve roots occurred two years later at p. 29 of "An Exposition of the Natural System of the Nerves of the Human Body" (1824).

So much for Magendie's attitude of mind towards Bell. But as is written at the head of these columns *Audi alteram partem*, let us therefore consider Bell's attitude of mind towards Magendie. Bell's rejoinder to Magendie's claim is given in the second part of his paper on the Nerves of the Orbit in the Philosophical Transactions of the Royal Society for 1823 at pages 302 and 307:—

> Experiments have never been the means of discovery, and a survey of what has been attempted of late years in physiology will prove that the opening of living animals has done more to perpetuate error than to confirm the just views taken from the study of anatomy and natural motions.
>
> Surely it is time that the schools of this kingdom should be distinguished from those of France. Let physiologists of that country borrow from us, and follow up our opinions by experiments (see the experiments of Magendie on the distinction in the roots of the spinal nerves), but let us continue to build that structure which has been commenced in the labours of the Monros and Hunters.

I earmark this passage as conveying Sir Charles Bell's opinion of Magendie.

Magendie replied to these comments in the tenth volume (1830) of his *Journal de Physiologie*, in a footnote prefatory to the translation of Bell's paper on the Nerve of the Face, of May 28th, 1829, as follows:—

> Je me suis toujours fait un devoir de presenter aux lecteurs de ce Journal les travaux anatomiques de M. Ch. Bell. Son esprit investigateur bien qu'un peu spéculatif, sa grande habileté dans l'art de disséquer, et son rare talent pour le dessin, lui assureront toujours une place distinguée parmi les anatomists de notre époque. Pourquoi faut-il que ce savant nuise à ses travaux, se nuise à lui-même, en ne rendant pas à ses émules la justice qui leur est due? Pourquoi conserve-t-il ce patriotisme barbare qui repousse tout ce qui n'est pas du pays? Pourquoi garde-t-il des prétentions à des découvertes qu'il n'a pas faites? Sans doute parce que tel est son caractère, et qu'il n'est pas facile de se changer, quand même on en sentirait le désir. D'ailleurs, ce travers, que notre franchise se permet de blâmer en lui, est peut-être le mobile qui l'excite au travail—et alors voudrions-nous réellement qu'il ne l'eut pas?

I earmark this passage as conveying Magendie's opinion of Sir Charles Bell. I have not attempted to translate it—the language is as clear and fine as is the thought.

The "dispute," if we are to call it so, is somewhat ancient. But so long as the essential facts exist on record it cannot be regarded as closed by a gross injustice, whether to a "countryman" or to a "foreigner." In a matter of such importance as the functional distinction between motor and sensory nerves historical truth is necessary and justice must be done to the "rival claims" of Bell and of Magendie in this respect. And if, as I believe, justice is due to Magendie, it is due to our own self-respect that such justice should be rendered in our own language.

I am, Sir, yours faithfully,

A. D. WALLER.

Physiological Laboratory, University of London, S.W., March 18th, 1911.

[1] "It was necessary to know, in the first place, whether the phenomena exhibited on injuring the separate roots of the spinal nerves corresponded with what was suggested by their anatomy. After delaying long on account of the unpleasant nature of the operation, I opened the spinal canal of a rabbit and cut the posterior roots of the nerves of the lower extremity; the creature crawled, but I was deterred from repeating the experiment by the protracted cruelty of the dissection. I reflected that an experiment would be satisfactory, if done on an animal recently knocked down and insensible; that whilst I experimented on a living animal there might be a trembling or action exerted in the muscles by touching a sensitive nerve, which motion it would be difficult to distinguish from that produced more immediately through the influence of the motor nerves. I therefore struck a rabbit behind the ear so as to deprive it of sensibility by the concussion, and then exposed the spinal marrow. On irritating the posterior roots of the nerve I could perceive no motion consequent on any part of the muscular frame; but on irritating the anterior roots of the nerve, at each touch of the forceps there was a corresponding motion of the muscles to which the nerve was distributed. These experiments satisfied me that the different roots and different columns from whence those roots arose were devoted to distinct offices, and that the notions drawn from the anatomy were correct."

## DEAF CHILDREN.

*To the Editor of* THE LANCET.

SIR,—May I be allowed to supplement the reference in the leading article on the education of deaf children appearing in THE LANCET of March 11th to the school of the Association for the Oral Instruction of the Deaf and Dumb at Fitzroy-square by a short statement as to the association's aims and its present position?

The writer of the article in question rightly points out that as early as the seventeenth century Dr. John Wallis of Oxford taught speech to his deaf pupils. So, too, did his contemporary Dr. William Holder of Bletchington. A century later the renowned Thomas Braidwood opened his private academy in Edinburgh, transferring it in 1783 to Hackney, London. Braidwood's method was founded on that of Wallis, and in its turn formed the basis of that of his nephew, Dr. Joseph Watson, who was the principal of the first English public school for indigent deaf children, founded in 1792 in the Old Kent-road, London. But oralism gradually waned, until in the "sixties" of last century the French system of signs was dominant in all the schools of the country.

Hence arose the association at Fitzroy-square, founded

in 1870, with the object of establishing a pure oral school for deaf children and a training college for teachers of the deaf on the oral method, and by these means of reintroducing into the country generally the practice of the oral instruction of deaf children.

Both the school and the training college have continued their work uninterruptedly down to the present time, mainly through the benevolence of a generous public. It is, however, to the training college I now wish to call attention, as the committee find themselves confronted with a task of exceptional difficulty in their endeavour to develop this side of the association's activities. That the college has been faithfully administered and successfully conducted may perhaps be best indicated in a word by stating that every Fitzroy-square student presented for the professional examination held by the joint examination board for teachers of the deaf, and open to candidates from all parts of the British Isles, has satisfied the requirements of the examiners, and one of them has each year headed the list of successful candidates. The work of the college has, however, been conducted under constant financial strain, and at no time has this strain been more severe than it is at the present moment. The college buildings are now inadequate for their purpose, and, further than this, the committee desire to broaden the basis of instruction given to the students and provide a training which shall not only satisfy the strictly technical requirements of teachers who seek service in certified schools for deaf children, but give them that degree of general culture and professional skill as will enable them to undertake with the fullest measure of competency the very important work to which they intend devoting their lives. *The State gives no grant towards the college expenses;* consequently fees have to be charged and the benevolent public appealed to from time to time.

An appeal is now being made for £3000, sufficient for the time being to enable the committee to carry out their proposals in a modest manner, though not to place the work on a permanent footing, and so far a fund has been collected amounting to about £1800. If the public could but realise the essential importance of an adequate supply of properly trained teachers, capable of giving the deaf children of the country a sound oral education, I feel sure the money would be forthcoming for our purposes. It is not enough that schools shall be opened and children compelled to attend them. They must also be staffed with properly trained teachers, and surely the work of providing the necessary training is one worthy of the most liberal endowment.

Mr. Macleod Yearsley's excellent articles on the education of the deaf child, which have just appeared in your journal, will, I trust, help not only to remove widespread misconceptions of the deaf child's educational capabilities and of his possibilities for useful citizenship, and bring about a better classification of deaf children at school, but help the public to realise how important the work of instructing these afflicted children is, and inferentially how essential it is that there should be a proper supply of competent teachers to undertake their instruction.

I am, Sir, yours faithfully,

G. SIBLEY HAYCOCK.

Fitzroy-square, London, W., March 15th, 1911.

## THE SPHYGMOMANOMETER AND THE SPHYGMOGRAPH IN RELATION TO THE MEASUREMENT OF ARTERIAL BLOOD PRESSURES.

*To the Editor of* THE LANCET.

SIR,—I am indebted to Dr. George Oliver for his generous recognition of my address on "The Sphygmomanometer and the Sphygmograph in Relation to the Measurement of Arterial Blood Pressures," and I am, of course, glad to have the advantage of his support. Doubtless, as he says, the multiplication of the time points of the arterial cycle at which "pressure" may be read will increase the clinical value of the sphygmomanometer, but even when the maximum and minimum can each be estimated with confidence the rapidity, or otherwise, of the movement from one to the other will still be beyond the resources of the instruments at present at our disposal. Since Dr. Oliver's demonstration at the Royal Society of Medicine I have had some experience of the ingenious apparatus he has given us, and so far there does seem to me some presumptive evidence that by the auditory method, leaving on one side the question of the resistance offered by the arterial wall, a measurement of the diastolic pressure may perhaps be effected. At least, in all cases in which I have found the maximum record abnormally high Dr. Oliver's tambour has indicated also a high diastolic reading, with one exception, and that a decidedly impressive one—namely, cases of aortic regurgitation. In these, in my experience, the tambour gives a very low figure as the diastolic record, sometimes, indeed, at, or close to, zero. As in aortic regurgitation the physical conditions are particularly favourable to the fall of the intra-arterial pressure during cardiac diastole to an unusually low level, the fact that in such cases the auditory method announces a very low "diastolic pressure" may reasonably, if confirmed, be quoted in support of the claim that by this method the "diastolic pressure" may be estimated.

Dr. Reginald Pratt (THE LANCET, March 18th, p. 765) raises another issue. He challenges without qualification the whole art of sphygmometry. Now it is no doubt true that the sphygmograph, like other apparatus, may be deliberately manipulated for a particular purpose, or may, in careless or inexperienced hands, yield, within limits, unreliable results. But these possible inaccuracies can be avoided by due attention and practice, and defects due to one or other of them can, for the most part, be detected, not only at the time of record, but even in the completed sphygmogram. For example, I feel sure that anyone accustomed to the use of the sphygmograph will readily recognise that the peculiarities of Dr. Pratt's tracing B depend on some artificial limitation of the free movement of the lever of the sphygmograph. The difference between his tracings A and B is not that one shows "ill-sustained pressure" and the other "well-sustained pressure," but that A has been taken with a sphygmograph so adjusted as to allow free movement of the lever, whereas B is the expression of a checked or limited movement. I do not know under what guidance Dr. Pratt recognises A as answering to the description of a "low tension" or "ill-sustained" pulse, but personally I should not, from a contemplation of the tracing, have come to this conclusion.

I am, Sir, yours faithfully,

Harley-street, W., March 20th, 1911. C. O. HAWTHORNE.

## "606" AND SYPHILIS.

*To the Editor of* THE LANCET.

SIR,—Allow me to make a few remarks in reply to the criticism of my article on "606"[1] by Dr. James McIntosh and Dr. Paul Fildes, published in THE LANCET of March 18th. In the first place, I must object to their accusation of my having cast a slur on the name of the inventor of "606." In my article I expressly stated that, "as its inventor is one who holds a high position as a medical scientist, it is necessary to deal with this preparation on its merits." As to the manner in which this preparation was "boomed," I do not know who was responsible for this, and I am not the only one who has drawn attention to it. In the second place, I beg to state that the views expressed in my article, which Dr. McIntosh and Dr. Fildes say are "unjustified and at variance with the opinions of the vast majority of competent observers," are shared to a greater or less extent by many experienced syphilologists and other members of the profession who are certainly competent. Whether these views are unjustified or not time will show; at any rate, the time appears opportune for a little wholesome criticism. After this preamble, I will pass on to the consideration of some of the statements made by Dr. McIntosh and Dr. Fildes.

1. These authors remark that "on the average, if not invariably, '606' is far superior to mercury in the symptomatic treatment of syphilis"; yet, in a previous paragraph, they state that "'606' has no reference to symptoms—it is purely a parasiticide." How these two statements can be reconciled is not apparent. But if "606" is purely a parasiticide, I should like to ask Dr. McIntosh and Dr. Fildes

[1] THE LANCET, Feb. 25th, 1911.

how they explain the undoubted healing effect of this preparation in cases of malignant syphilis, in the lesions of which, according to Buschke,[2] spirochætes are absent. The explanation given by Buschke is that the action of arsenobenzol is not parasitotropic, as Ehrlich supposed, but organotropic, and that it acts in a similar way to mercury and iodides. This view also applies to the lesions of tertiary syphilis, in which spirochætes are absent or few in number. I may add here that Dr. McIntosh and Dr. Fildes's assumption that, in my statement that treatment by "606" is symptomatic only and "not treatment of the disease itself," I "refer apparently to the spirochæte," is incorrect; the spirochæte is by no means the only factor concerned in syphilis, as Sir Jonathan Hutchinson has well pointed out in the new edition of his book. Dr. Levy-Bing,[3] who has just published the results of six months' experience with intramuscular injections of "606" at the St. Lazare Hospital, Paris, also comes to the conclusion that this preparation only cures the symptoms of syphilis, not the disease itself.

2. Dr. McIntosh and Dr. Fildes consider that "'606,' applied at properly ascertained times, will prevent the onset of symptoms with far less inconvenience and effect upon the general health than mercury." But, so far, there is no evidence that "606" has any action in preventing the onset of symptoms; in fact, according to Levy-Bing, recurrent symptoms are more frequent, and often of greater severity, after treatment by "606" than after mercurial treatment. With regard to the effect of mercury on the general health, so far as my experience goes (and this agrees with that of Sir Jonathan Hutchinson) the general health is generally improved by a course of mercury.

3. Dr. McIntosh and Dr. Fildes are undoubtedly correct in stating that "'606' will probably be used by the unskilled," but that this will be "without danger" is hardly to be believed. Apart from the deaths and other severe accidents following the injection of this preparation, which may in part, I admit, be attributed to faulty technique, there is an increasing amount of evidence to show that "606" has a deleterious effect on the nerves. This neurotropic action has been pointed out by Buschke and Fischer,[4] Finger,[5] Stern,[6] and others, who have reported cases of paralysis of the ocular muscles and affections of the internal ear. Buschke even goes so far as to consider that, in addition to the directly injurious effects of arsenic, "606" may cause deposits of arsenic in the internal organs, which predispose to further manifestations of syphilis. Finger, on account of this neurotropic action of "606," does not consider it indicated for the ordinary treatment of syphilis. "Aus den Gesagten glaube ich zum Schlusse kommen zu sollen, dass das Arsenobenzol sich vorläufig zur Anwendung in der Praxis nicht eignet."

I am, Sir, yours faithfully,

London, N.W., March 18th, 1911. C. F. MARSHALL.

## "TERRIBLE NEWS OF THE PLAGUE."

*To the Editor of* THE LANCET.

SIR,—I have read in this week's issue of THE LANCET a report from St. Petersburg forwarded by your Constantinople correspondent and entitled "Terrible News of the Plague." The news may be terrible, but is not in any way founded on fact. I have but a few days ago returned from Peking, travelling through Manchuria, and when at Mukden met two of the workers from Harbin—namely, Dr. Wu and Dr. J. M. Stenhouse—so that I had ample opportunity of learning about the exact position of affairs.

As has been already reported by your China correspondent, active and effectual antiplague work has been carried on in the Chinese town of Harbin (Fuchiatien) for the last two months or more by Dr. Wu and other Chinese doctors, assisted by Dr. J. G. Gibb, Dr. W. H. G. Aspland, and Dr. Stenhouse, who are colleagues of my own at the Union Medical College, Peking. At the beginning of February the death-rate in Fuchiatien was as high as 150 a day, but since then conditions have steadily improved, so that at the time of my leaving (Feb. 28th) it had fallen as low as only two a day.

When these doctors first went up to Harbin the work was much obstructed by some of the local officials. Subsequently, by orders from Peking, these men were degraded, and thereafter the governor of the province and other officials did everything in their power to help the medical men in charge. The bodies of the dead were burnt to the number of about 4000, and have not been left lying about the streets as your correspondent describes. A large and efficient staff of sanitary police has been employed, while house-to-house inspection, rehousing, and isolation work have been steadily carried on, with the very satisfactory results described above. Naturally, the distress and suffering have been very great, but more from the intense cold and entire dislocation of trade than even from the plague itself. It is these conditions which have made the work so extremely difficult. Part of the Chinese Town had to be burnt down and large numbers of people had to be temporarily housed, whilst many more, as could only be expected and unfortunately could not be prevented, scattered to other parts of the country. In consequence, the town is in some measure deserted at the present time.

It is a pity, however, that these reports sent from St. Petersburg should be so inaccurate and misleading, as they bring discredit on the excellent work which has been done and which has been fully acknowledged by the Russian medical authorities. Similar reports have previously been circulated through St. Petersburg, an example occurring only the other day, when it was stated that 18 out of 19 Chinese doctors had died of plague at Kuanchengtze. The facts subsequently telegraphed by Dr. Young, also of the Union Medical College, Peking, were as follows: "Hospital under native doctors closed because four nurses, two doctors died. No precautions observed." This probably refers to a hospital manned by untrained Chinese doctors, many of whom have served bravely and faithfully in spite of their insufficiency of medical knowledge.

Before leaving Peking at the end of February I had abundant opportunity of seeing and hearing about the work done to prevent the spread of the plague. In consequence of ignorance of the danger and of the grievous insufficiency of trained medical men, the work was begun late and carried out under many difficulties; but, speaking generally, the necessary measures were widely and gladly adopted and the officials heartily coöperated in the work. It is to be hoped, however, that the present circumstances will help to awaken the Chinese Government and people to the intense need of national public health work, and of efficiently trained men to carry this out. I am, Sir, yours faithfully,

H. V. WENHAM.

St. Bartholomew's Hospital, London, E.C., March 18th, 1911.

## OPEN WINDOWS IN THE TREATMENT OF CERTAIN DISEASES.

*To the Editor of* THE LANCET.

SIR,—About three years ago I called attention to certain facts which seemed to indicate that the prevalence of adenoids among children resulted from making them sleep during cold and damp weather with the windows open. Among other things I then noted, of 49 children who had been brought up strictly on the open-window system 22 had been operated on for adenoids, while in 69 children who had been brought up on the shut-window system only two cases of adenoids were observed. Further investigation seems to me to have confirmed the supposition that cold and damp air predisposes to, or is in some way generally associated with, the causation of adenoids, and I understand that some laryngologists now admit my contention. Indeed, one told me that he was now "absolutely convinced," and another that he had been "completely converted."

Further considerations have led me to suspect the wisdom of treating certain diseases on the open-window system. That cold and damp weather has a very marked effect on the prevalence and severity of certain diseases is conclusively shown by the frequency of these diseases in winter and the mortality returns at particular periods of the year associated with cold and damp weather. On the other hand, as far as I have been able to learn, there are no satisfactory statistics which indicate that the open-window treatment of influenza, common colds, measles, and bronchitis is attended with more beneficent results than the shut-window system. The

[5] Wiener Klinische Wochenschrift, Nov. 24th, 1910.
[6] Deutsche Medizinische Wochenschrift, Jan. 5th, 1911.

prevalence of such a deadly disease as pneumonia so frequently following some of the diseases referred to indicates that we should at least have some very definite statistical evidence as to the effect of the open-window system in the treatment of these diseases during cold and damp weather. Of course, I am not suggesting that efficient ventilation by night as well as by day is not desirable, nor that there may not be more chance of infection for others in the same room, if the windows are kept closed, nor even that in good health it is not desirable to become hardened as far as possible to the ordinary climatic variations which are likely to have to be encountered. My point is, that when any of the diseases mentioned is present that is not the time, in the majority of cases at least, for anything but sheltering the patient from certain climatic vicissitudes. Open windows are particularly objectionable in all probability when a child is ill and has hitherto not been habituated to the pouring in of cold and damp air through the open window. It would appear, however, that one of the first things which may be done, immediately a nurse for a sick child has been procured, is to open, and keep open, the windows day and night regardless of the nature of the disease, the kind of weather or the conditions to which the child may hitherto have been accustomed. I am, Sir, yours faithfully,

Wimpole-street, W., March 7th, 1911. J. SIM WALLACE.

## EYE-STRAIN IN RELATION TO GENERAL HEALTH.

*To the Editor of* THE LANCET.

SIR,—It is not easy to grasp the point of Mr. Kenneth Campbell's letter in THE LANCET of March 18th. I take it he admits the possibility of local cerebral congestion, though contradicted by experimental research, and denies that such a factor could cause the symptoms usually attributed to "eye-strain" "in view of the fact that the brain is insensitive." Headache is one of the commonest results of so-called "eye-strain," it is also the result of many other conditions—toxic, traumatic, &c. If then the sensitiveness of the brain has anything to do with the subject I would be glad to hear in what way. I am, Sir, yours faithfully,

Manchester, March 20th, 1911. A. A. BRADBURNE.

## EXPERIMENTS IN SEWER VENTILATION AT LEICESTER.

*To the Editor of* THE LANCET.

SIR,—The report of your Sanitary Commissioner in THE LANCET of March 4th, p. 618, points once more to the efforts of THE LANCET in continually making publicly known anything likely to assist in improving the health and comfort of the people all over the world in general and of the United Kingdom in particular. The truly scientific system of sewer and drain ventilation of Shones cannot be questioned by any practical man, and it is a great pity it is not more largely adopted throughout the kingdom, especially in so-called health towns, which should be compelled by Act of Parliament to have every drain and sewer fitted or a similarly effectual system.

Your Commissioner in his very thorough report calls attention to the difficulties encountered at Leicester after the system had been put in operation, especially when it was found that air was drawn into the drains and sewer through unsound and leaky joints and not through the down-cast ventilation pipes. To my mind, this is evidence of one of the valuable points of the system, because it exhibits a serious weakness that under the present system of sewer or drain ventilation would never be discovered, especially as now there are methods of making drain and pipe sewer joints sound (air and water tight) without greatly disturbing the surface ground under which drains and sewers are laid at a reasonable cost. The very great health advantage would be added to the district of having sound sewers and drains scientifically ventilated, with the advantage, as your Commissioner also points out, of having all foul smells drafted away from the town and district where they can be filtered, cremated, or destroyed. Another great advantage also accrues in that the sewage is continually being aerated, and in places where sewers have slight gradients the flow would be doubtlessly accelerated. Your Commissioner mentions cost of electric current at 3*d.* per unit, but now in most places where an efficient installation of electricity is obtained the cost for power should not be more than 1½*d.* per unit, and to avoid another risk also mentioned—viz., failure of ventilation by breakdown of motor working the fans—the motors and fans should be in duplicate.

As in my experience there are very few places where drains and sewers are sound, the value is seen of adopting some such system of sewer ventilation so nobly tried by the advanced town of Leicester, and so ably explained by your Sanitary Commissioner, and the wide publication of your report should tempt some of our good philanthropists who have the good health of the nation one of their objects.

I am, Sir, yours faithfully,

Ebury-street, London, S.W., March 8th, 1911. D. T. BOSTEL.

## A DISCLAIMER.

*To the Editor of* THE LANCET.

SIR,—Mr. Dixon, a Christian Scientist, lately said in the *Saturday Review* that I "declared openly, a few months ago, that there is such a mania for the removal of the appendix." Let me say that I never said anything of the kind, nor wrote it, anywhere. Mr. Dixon is attributing to me what somebody else may have said.—I am, Sir, yours faithfully,

Ladbroke-square, W., March 21st, 1911. STEPHEN PAGET.

## MUSCULAR SPASM IN CARIES OF THE SPINE.

*To the Editor of* THE LANCET.

SIR,—While being naturally gratified at the appreciation of my work, which so well-known an authority on spinal curvatures as Mr. Roth has been kind enough to express, I must confess some surprise at his protest against my suggestion that muscular spasm is a factor of importance in the production of deformity in spinal caries.

Mr. Roth's assertion that I have assumed the action of a whole group of muscles which do not exist is unwarranted; his appeal to you to admit that such muscles exist only in my imagination is almost pathetic; while his sneer at an eminent orthopædic surgeon, whose views may not coincide with his own, is undignified. Mr. Roth has not appreciated the fact that an anterior spinal muscle is by no means synonymous with a muscle anterior to the spine. In the paper he refers to, which you honoured me by printing in the columns of THE LANCET, I was dealing essentially with the mechanical treatment of spinal caries during recumbency. I indeed prefaced my description of the apparatus I employ by a short allusion to the factors which produce deformity, and emphasised the influence of muscular spasm. That it is a factor in the production of deformity of extreme importance I am convinced, but that its action is very complex, I think, cannot be doubted. I hope indeed later to be able to publish a separate paper on this subject, but to have dealt with it at length in the original paper was an impossibility.

Mr. Roth has deigned to criticise my remarks somewhat hastily and without due consideration. If he will dispassionately consider the factors which produce deformity in spinal caries in any particular case, he should, in the light of the suggestion I have made as to the importance of muscular spasm, soon grasp the importance of the action of the anterior spinal muscles—i.e., the anterior of the muscles investing the spine—which act to the greatest mechanical advantage in the dorsal region, and not, as he conceives they should, in the cervical or lumbar. Mr. Roth has betrayed a lack of comprehension of muscular action about the spine. Perhaps his kindly hint that I should examine the cadaver might be amicably reciprocated by me. I did not venture to advance my views until I had anticipated his advice and supplemented the information I thus gained by extensive clinical observation.

In any case, even if Mr. Roth is unable to appreciate the effects of muscular spasm in spinal caries, yet still he may care to adopt the mechanical methods I have advocated, methods which are the outcome of a study of muscular spasm in this condition. In that case I can promise him with confidence that the cases of spinal caries under his care will not become more deformed, that deformity which has not commenced will not appear, and that that portion of deformity which may be present which is due to existing muscular spasm may be safely and certainly corrected.

I am, Sir, yours faithfully,

Alton, Hants, March 20th, 1911. H. J. GAUVAIN.

# THE CHOLERA EPIDEMIC.

(BY THE BRITISH DELEGATE TO THE CONSTANTINOPLE BOARD OF HEALTH.)

*Cholera in Russia.*

CHOLERA still lingers in Russia, as shown by the following returns (in continuation of the figures published in my last letter in THE LANCET of Feb. 11th, p. 395):—

| | | | | | | |
|---|---|---|---|---|---|---|
| Week ending Nov. | 20th | ..... | 30 | cases, | 16 | deaths. |
| ,, ,, | ,, 27th | ..... | 34 | ,, | 18 | ,, |
| ,, ,, | Dec. 4th | ..... | 13 | ,, | 9 | ,, |
| ,, ,, | ,, 11th | ..... | 37 | ,, | 18 | ,, |
| ,, ,, | ,, 18th | ..... | 14 | ,, | 5 | ,, |
| ,, ,, | ,, 25th | ..... | 2 | ,, | 3 | ,, |

The above are "corrected" figures; the following are "uncorrected":—

| | | | | | | |
|---|---|---|---|---|---|---|
| Week ending Jan. | 1st | ..... | 4 | cases, | 1 | death. |
| ,, ,, | ,, 8th | ..... | 2 | ,, | 4 | ,, |
| ,, ,, | ,, 15th | ..... | 9 | ,, | 6 | ,, |
| ,, ,, | ,, 22nd | ..... | 2 | ,, | 1 | ,, |

The cases and deaths in the bulletins for Jan. 1st and 8th all occurred in the Ekaterinoslav government, those in the bulletin for Jan. 15th in the governments of Podolia and Kief, and those in the bulletin for Jan. 22nd in the government of Podolia. (All the above dates are according to the Old Style.)

*Cholera in Austria.*

On Dec. 10th the Austrian Minister of the Interior declared officially that no case of cholera had occurred on Austrian soil since Nov. 7th, and that from the beginning of the outbreak on August 23rd there had been only 15 cases with 5 deaths. The last case was that of a major in the army, who arrived at Graz on Nov. 5th and was apparently already sickening with an attack of cholera; he had come from Pancsova, in the county of Torontal, which had already been declared an infected district.

*Cholera in Hungary.*

On Dec. 30th it was officially stated that no fresh case of cholera had occurred in any part of Hungary—Croatia and Slavonia included—for five days, and the whole country was declared "clean." The following additional figures have been received for the outbreak in Croatia and Slavonia:—Between Nov. 5th and 12th there were 9 cases and 8 deaths, occurring in six different places, situated in five different counties; between Nov. 12th and 19th there were 11 cases and 4 deaths in six places, in four different counties; and between Nov. 19th and 26th there were 4 cases and 2 deaths in four places. All these cases were confirmed bacteriologically. Between Nov. 26th and Dec. 4th no further cases occurred; but between the 4th and 10th 2 cases, both fatal, occurred in the county of Srien, and between the 10th and 17th 1 case in that of Agram.

*Cholera in Italy.*

The latest returns from Italy are as follows:—In the week ending Dec. 14th 38 cases and 11 deaths; of these, 3 cases and 1 death occurred in the province of Aquila, 1 case in that of Caltanisetta, 9 cases and 4 deaths in that of Caserta, 6 cases and 1 death in that of Lecce, 9 cases and 2 deaths in that of Palermo (including 7 cases and 1 death in the Palermo lunatic asylum), 3 cases and 3 deaths in that of Rome, and 7 cases in that of Salerno. In the week ending Dec. 21st there were 18 cases and 2 deaths, distributed as follows:—1 case and 1 death in the province of Caltanisetta, 4 cases in that of Caserta, 9 cases in that of Lecce, 3 cases and 1 death in that of Palermo (all in the asylum above alluded to), and 1 case in that of Salerno. No detailed returns have been received here since the last-named date, but it is declared officially that since Jan. 31st no further case of cholera has occurred on Italian territory.

*Cholera in Constantinople and Turkey in Europe.*

The cholera outbreak in this city came to an end early in January. In the week ending Jan. 2nd there had been 62 cases and 46 deaths; in that ending Jan. 9th the figures fell to 17 cases and 20 deaths; and between the 10th and 13th 10 more cases and 8 deaths were registered. The last new case occurred on the 11th, and ten days later Constantinople was declared free. The totals since the beginning of the epidemic on Sept. 13th were placed at 1318 cases and 793 deaths, among the civil population. Since the middle of January remarkably severe weather has been prevalent in Constantinople and neighbourhood. In Salonica no cases have been reported since Dec. 31st, and the whole of European Turkey seems to be now free from cholera.

*Cholera in Asiatic Turkey and among Returning Pilgrims.*

The following have been the recent weekly returns from Smyrna:—

| | | | | | | |
|---|---|---|---|---|---|---|
| Week ending Jan. | 1st | ..... | 12 | cases, | 8 | deaths. |
| ,, ,, | ,, 8th | ..... | 36 | ,, | 20 | ,, |
| ,, ,, | ,, 15th | ..... | 38 | ,, | 27 | ,, |
| ,, ,, | ,, 22nd | ..... | 86 | ,, | 51 | ,, |
| ,, ,, | ,, 29th | ..... | 69 | ,, | 32 | ,, |
| ,, ,, | Feb. 5th | ..... | 15 | ,, | 11 | ,, |
| ,, ,, | ,, 12th | ..... | 5 | ,, | 3 | ,, |

The last case here occurred on the 7th, and Smyrna has now been declared cholera-free. In all 341 cases and 213 deaths have been recorded in the town. Recently a few cases of suspected cholera have occurred in the neighbourhood of Broussa, and in that of Zunguldak on the Black Sea. Otherwise the whole of Asia Minor appears to be now free from the disease. The same statement may be made in regard to the Bagdad vilayet; 5 cases and 5 deaths occurred here (at Kerbela, one of the Shiah holy cities) on Jan. 1st and 2nd, and none have been reported since. The outbreak of cholera among the returning pilgrims, the beginning of which was reported in my last letter, has caused a considerable, but not excessively high, mortality. In Mecca the following cases and deaths have been recorded:—

| | | | | | | |
|---|---|---|---|---|---|---|
| Between Dec. 26th and Jan. 15th | ..... | 119 | cases, | 106 | deaths. |
| ,, Jan. 16th ,, | ,, 22nd | ..... | 24 | ,, | 26 | ,, |
| ,, ,, 23rd ,, | ,, 28th | ..... | 10 | ,, | 10 | ,, |

Since the last-named date Mecca appears to have been free from the disease. The totals here are put at 153 cases with 142 deaths. These figures are in all probability below the truth. In Jeddah the disease was first seen about Jan. 10th; the first cases occurred among the troops. The outbreak in this port seems to have been limited to about a score of cases, and on Feb. 9th it was telegraphed that no further cholera bulletins would be issued, the outbreak appearing to be at an end. From Yanbo only irregular and imperfect reports have been received; on Jan. 8th it was reported that 7 cases and 2 deaths had occurred there; and on Jan. 13th the totals were said to be 24 cases and 21 deaths. No further news has been received from Yanbo. An outbreak of cholera, in regard to which it has proved difficult to obtain exact information, has occurred in the Yemen, in the neighbourhood of Hodeidah. The first cases were seen in the village of Badjil, 25 miles to the north-east of Hodeidah; between Jan. 9th and 16th 48 cases of cholera and 37 deaths were recorded here; two fatal cases were also seen at Zeidieh, a village to the north. Between the 16th and 21st 10 further cases, with 9 deaths, occurred at Badjil. On the 21st it was reported that cholera, "confirmed bacteriologically," was prevalent among the troops in Hodeidah, causing many cases and deaths; that 3 cases and 2 deaths had occurred among the native population; and that it was reported "unofficially" that cholera existed among the troops at Menaha. Three cases of the disease occurred in the Camaran lazaret, among pilgrims returning to the Yemen and carried on board the s.s. *Budrie;* the first case was isolated on Jan. 8th, the second on the 9th, and the third on the 17th. Vice-consular reports from Hodeidah also state that cholera had, according to "unofficial" reports, broken out among recruits on a transport steamer, the s.s. *Saiyar*, and that between Jan. 17th and 19th 50 cases of the disease and 18 deaths had occurred among them. Large numbers of troops are still being poured into the Yemen, where the bulk of the Arab tribes are in revolt, and it is generally believed that both the Turkish army and the Arabs are suffering from a more or less severe outbreak of cholera; but, as already stated, it is most difficult to learn the true facts. As was anticipated, the infection was carried from Mecca to Medina by the caravans of returning pilgrims. Apparently the first infected group arrived at Medina on Jan. 4th; it had had 5 cases and 4 deaths from cholera. Succeeding caravans arrived in the same condition; they reported that the disease had appeared

among them at Rabigh (or Rabouk)—the important point on the most westerly of the three roads from Mecca to Medina, and the spot where it is generally thought a new port will some day be made, destined to replace Jeddah, and perhaps to be the terminus of the railway between Mecca and the coast. On the 10th as many as 14,000 pilgrims arrived from Mecca in the day, and 51 cases of cholera with 25 deaths were recorded among them. The disease also prevailed among the inhabitants of the town, and a score or so of cases occurred daily for some time. By Jan. 27th 400 cases and 510 deaths had been registered. It may be noted that infected caravans continued to arrive from Mecca, both by the most westerly and the most easterly roads; and that among some 7000 pilgrims arriving in Medina from Yanbo no case of cholera occurred, showing that in all probability the outbreak at Yanbo has not been a very severe one. The latest returns from Medina show that only 3 or 4 cases are occurring there daily.

*Cholera on the Hedjaz Railway.*

The first pilgrim train left Medina for the north on Jan. 5th, with 429 pilgrims. Groups of from 300 to 500 pilgrims continued steadily to arrive at the Tebuk lazaret once or twice a day. Among the first groups to reach the lazaret three suspected cholera cases occurred, and these were subsequently confirmed bacteriologically. Since then apparently no cases of the disease have been seen there. It has to be remembered that the Tebuk lazaret is still an improvised one, though it already possesses most of the essentials of such an institution. Some alarm was created recently by the report that cholera had occurred among pilgrims arriving at Damascus, after having done their quarantine and other measures at Tebuk; but fortunately this report appears to have been quite unfounded, and so far as is known no case of cholera has yet occurred north of the lazaret of Tebuk. Some suspicious cases have been more than once reported as occurring in the trains between Tebuk and Damascus, but none of these have been confirmed; indeed, they have all been officially declared not to have been cases of cholera. The pilgrims are subjected to a final medical visit on their arrival at the Kadem terminus of the railway in Damascus. The movement northwards of pilgrims still continues, and so long as it continues there must always be a danger of cholera appearing among them at Damascus or elsewhere, in spite of the measures executed at Tebuk.

*Cholera in Persia.*

Cholera appears to have lingered in many parts of Persia throughout the month of December. A telegram from Teheran, dated Jan. 7th, stated that cholera "existed positively" at the end of December in the towns of Hamadan, Kerman, and Mohammera, and that, "according to all appearances," the provinces of Ghilan, Kaskin (? Kazvin), Khorassan and Kaian (?) were not yet completely free from the disease. On Jan. 22nd another telegram stated that no case had occurred in any part of Persia since the 20th.

Constantinople, Feb. 17th.

## THE DANGEROUS WATER-SUPPLY OF CHERBOURG.

(FROM A CORRESPONDENT.)

CHERBOURG, the French naval port, lies at the mouth of the river Divette, and in the lower part of its basin. It is a town of some 43,000 inhabitants, of whom 16,000 are employed in the arsenal or are in the army or navy. It has a sinister reputation as the town in France, Toulon only excepted, the most seriously and constantly infected with enteric fever. The enteric death-rate of Toulon in the ten years 1897 to 1906 is stated at 0·86 per 1000 living, that of Cherbourg at 0·71 per 1000, while Paris only lost 0·15 per 1000 of her population by this disease. These figures are taken from a detailed account of an epidemic in Cherbourg in 1909, which appeared in December and January in the *Archives de Médecine Navale*, written by Dr. L. E. F. Brunet, Médecin de première classe. His tables show that enteric fever is every year present in Cherbourg, but that notable epidemics occurred amongst the Government employees of all kinds (the people who are treated in the naval hospital) in 1889, 1898 and 1899, and in 1909, and that every single epidemic was ascribed to the bad water-supply, which still remains ever the same. I think that readers of THE LANCET may find the story instructive.

Cherbourg gets its water-supply, it appears, mainly from the Divette, but also from brooks, from certain springs, and from wells. People who live just above the town use the Divette water exactly as they pump it up; the navy has a station a mile above the town where they take water from it—water they pipe to the arsenal for boilers, washing, and the like; just below this is the town's intake—the water is allowed to settle and is filtered before distribution as drinking water. Owing to the geological conditions of the district the springs cannot be secured against pollution, but from them the barracks are supplied, water intended for drinking being all sterilised before issue. Taps—"washing water only"—are frequent throughout the barracks and the arsenal, and men will make mistakes. Only one barrack has a supply in which bacillus coli has never yet been found, and its men got off very lightly in the last epidemic. The small houses of the district, cafés, public-houses, lodgings affected by soldiers and sailors generally get their water from wells which are all suspected; many have been closed as they contained too many of the bacillus coli. As to conservancy, there is no general system of water carriage, but there are a great number of leaking cesspools and many pail-closets. The nightsoil is spread on the fields in the valley of the Divette above the town or around the brooks mentioned, and it has been for long believed that the water becomes charged habitually with the bacillus coli and from time to time with the bacillus typhosus.

Medical men have for years been preaching about the terrible risk and the constant damage to the health of the garrison and of the townspeople involved in this lack of protection of the water-supply, but nothing thorough has been done. In 1889 there were 394 cases of enteric fever in the naval hospital with 75 deaths; the director of the naval board of health pointed out that it was not filters only, but a pure water-supply that was required, adding that it was the duty of the board of health to emphasise the dangers, but the duty of the superior authorities to remove them. A military medical officer, too, at the same time insisted on the need for pure water, but only Chamberland filters were installed. As far back as 1898 and 1899, 665 cases were treated in the naval hospital with 189 deaths, and Director Rouvier wrote that the navy must have good water for itself, and to shield its men from infection must require the town, too, to get a good supply. Yet the source of supply remains as before, only the army and navy sterilise some water for their men, and the town seems to purify its water in some degree by sedimentation and filtration. That is all that has been done. The dangers are so well known to the inhabitants that they avoid drinking the water as far as possible; some very scrupulously filter all they use, others buy the water of a particular spring, reputed safe, in bottles for drinking and personal washing; others, again, drink nothing but cider.

Cherbourg is always liable to an outburst of enteric fever, and some 30 deaths due to the disease occur there every year. The story of the epidemic of 1909 is a typically instructive one. On Jan. 7th a case of illness was received in the Naval Hospital and gave on the 11th a positive Widal reaction. Eight cases in all were received during January; they were from the arsenal. On Feb. 6th there came four men all from different parts of the district, showing that the whole of the water-supplies were infected, 65 were received in the first fortnight of February, 92 in the next fortnight, 59 and 69 in the successive fortnights of March, by which time the epidemic was nearly over, only 16 cases appeared in April, two in May, and six in the next three months. There were 317 cases altogether, of whom 58 died. It appears that the only body of men who conspicuously suffered little were the two regiments whose barracks rejoice in the water-supply free from bacillus coli (13 cases and two deaths between the two regiments). As soon as the existence of the epidemic was recognised all the emergency measures that could be taken to stop it were suggested by the doctors and at once put in orders. They could not be expected to make any difference for a fortnight or three weeks, and in the meantime everybody came to show sympathy with the sick. The Minister of Marine came, the Under-Secretary for War, many high functionaries, the Committee

to 14·9 per 1000, rose again to 15·4 in the week under notice. During the first 11 weeks of the current quarter the death-rate in these towns averaged 15·9 per 1000, and the mean recorded rate in London during the same period was also equal to 15·9. The annual death-rates during last week ranged from 4·9 in Handsworth, 5·3 in King's Norton, 7·6 in Wallasey, and 8·3 in Northampton, to 21·9 in Sheffield, 22·5 in Middlesbrough, 22·7 in Plymouth, and 23·3 in Coventry. The 5052 deaths from all causes in the 77 towns showed an increase of 141 upon the number returned in the previous week, and included 695 which were referred to the principal epidemic diseases, against numbers increasing from 477 to 702 in the five preceding weeks; of these 695 deaths, 460 resulted from measles, 109 from whooping-cough, 44 from diphtheria, 42 from infantile diarrhœa, 22 from scarlet fever, 17 from enteric fever, and 1 from small-pox. The annual death-rate in the 77 towns from these epidemic diseases averaged 2·1 per 1000. The fatal cases of measles, which had steadily increased from 160 to 474 in the first ten weeks of the current quarter, declined last week to 460; the highest annual death-rates from this disease among the 77 towns last week were 3·8 in Coventry, 4·1 in Plymouth, 5·4 in Devonport, 5·6 in Wigan, and 8·0 in Sheffield. The deaths from whooping-cough, which had been 108 and 80 in the two previous weeks, rose again to 109 last week; they caused the highest rates last week, 1·7 in Wigan, 1·8 in Aston Manor, and 1·9 in Coventry and in West Hartlepool. The 44 deaths from diphtheria showed a further decline of 12 from the numbers in recent weeks; they included 13 in London and its suburban districts, 4 in Leeds, and 3 both in Bristol and in Sheffield. The 42 deaths of infants under 2 years of age attributed to diarrhœa, showed a further decline from the numbers in recent weeks, and were fewer than in any previous week of this year. The 22 fatal cases of scarlet fever also showed a further decline from the numbers in recent weeks; 4 were recorded in London and 2 each in Liverpool, Stoke-on-Trent, and Bury. The deaths referred to enteric fever, which had been 15 and 13 in the two previous weeks, rose to 17 last week, of which 3 occurred in Manchester, 3 in Leeds, and 2 both in London and in Portsmouth. The fatal case of small-pox occurred in London, and was admitted to hospital from Poplar. The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospital, which had declined in the four preceding weeks from 1276 to 1166, had further fallen to 1121 on Saturday last; 146 new cases of this disease were admitted to these hospitals during last week, against 138, 129, and 120 in the three preceding weeks. These metropolitan hospitals also contained on Saturday last 920 cases of diphtheria, 822 of measles, 256 of whooping-cough, 32 of enteric fever, and 38 of small-pox. The 1419 deaths from all causes in London last week, an increase of 28 upon the number in the previous week, included 284 which were referred to diseases of the respiratory system, against numbers ranging from 421 to 318 in the four preceding weeks; 7 deaths were also referred to influenza. In the 77 towns 156 deaths from different forms of violence were registered during last week, against 173, 153, and 142 in the three preceding weeks; and 377 inquest cases were recorded. The causes of 46, or 0·9 per cent., of the deaths registered during the week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, Bristol, Bradford, Newcastle-on-Tyne, Nottingham, Leicester, Salford, and in 47 other smaller towns; the 46 uncertified causes of death in the 77 towns last week included 9 in Birmingham, 4 in Stoke-on-Trent, and 3 each in Liverpool, Sheffield, and Preston.

### HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 907 births and 617 deaths were registered during the week ending March 18th. The annual rate of mortality in these towns, which had steadily declined in the five preceding weeks from 19·8 to 15·9 per 1000, rose again to 16·8 in the week under notice. During the first 11 weeks of the current quarter the death-rate in these towns averaged 17·0 per 1000, and exceeded by 1·1 the mean rate during the same period in the 77 English towns. The annual death-rate last week in the eight Scotch towns ranged from 14·3 and 14·6 in Leith and Aberdeen to 20·1 in Dundee and 20·8 in Paisley. The 617 deaths from all causes in the eight towns last week showed an increase of 34 upon the number returned in the previous week, and included 66 which were referred to the principal epidemic diseases, against 76, 57, and 60 in the three preceding weeks; these 66 deaths were equal to an annual rate of 1·8 per 1000, which was 0·3 below the rate from the same diseases in the 77 English towns; the highest rates from these diseases in the Scotch towns last week were 3·3 in Paisley and 4·2 in Leith. Of these 66 deaths from epidemic diseases last week in the eight towns 36 resulted from whooping-cough, 11 from diarrhœa, 9 from diphtheria, 5 from scarlet fever, 4 from measles, and 1 from enteric fever, but not one from small-pox. The fatal cases of whooping-cough, which had been 32 and 36 in the two previous weeks, were again 36 last week, and included 15 in Glasgow, 5 each in Edinburgh, Paisley, and Leith, and 4 in Dundee. The 11 deaths attributed to diarrhœa (of which 10 were of infants under two years of age), exceeded the number in the previous week by 4, and included 5 both in Glasgow and in Dundee. The deaths referred to diphtheria, which had been 5 in each of the two previous weeks, rose to 9 last week; 4 occurred in Edinburgh and 3 in Glasgow. Of the 5 fatal cases of scarlet fever, 2 were recorded in Glasgow; and the 4 deaths from measles included 2 both in Glasgow and in Edinburgh. The death resulting from enteric fever was registered in Leith. The deaths referred to diseases of the respiratory system in the eight towns, which had declined in the four preceding weeks from 181 to 108, were 109 in the week under notice. The 18 deaths attributed to different forms of violence were within 2 of the number in the previous week; and 180, or 29 per cent., of the 617 deaths from all causes occurred in public institutions. The causes of 21, or 3·4 per cent., of the deaths registered in the eight towns during the week were not certified or not stated; in the 77 English towns last week the proportion of uncertified causes of death did not exceed 0·9 per cent.

### HEALTH OF IRISH TOWNS.

In the 22 town districts of Ireland, having an estimated population of 1,163,596 persons, 612 births and 389 deaths were registered during the week ending March 18th. The annual rate of mortality in these towns, which had steadily declined in the five preceding weeks from 24·1 to 19·3 per 1000, further fell to 17·4 in the week under notice. During the first 11 weeks of the current quarter the annual death-rate in these 22 towns averaged 20·4 per 1000; the rate during the same period did not exceed 15·9 in the 77 English towns, and 17·0 in the eight Scotch towns. The annual death-rate during last week was equal to 20·8 in Dublin, 15·4 in Belfast, 16·4 in Cork, 10·7 in Londonderry, 15·0 in Limerick, and 15·6 in Waterford; in the 16 smallest of the Irish towns the mean annual death-rate last week was equal to 17·2 per 1000. The 389 deaths from all causes in the 22 towns last week showed a further decline of 42 from the numbers returned in recent weeks and included 21 which were referred to the principal epidemic diseases, against 41, 25, and 26 in the three preceding weeks; these 21 deaths were equal to an annual rate of 0·9 per 1000, which was 1·2 below the mean rate from the same diseases in the 77 English towns. Of these 21 deaths in the Irish towns from the principal epidemic diseases, 8 resulted from measles, 6 from diarrhœa, 5 from whooping-cough, and 1 each from scarlet fever and enteric fever, but not one either from small-pox or diphtheria. The 8 fatal cases of measles, of which 7 occurred in Dublin and 1 in Drogheda, showed an increase of one on the number in the previous week. The 5 deaths from whooping-cough showed a further considerable decline from the numbers in recent weeks; they included 4 in Dublin and 1 in Belfast. Five of the 6 deaths attributed to diarrhœa occurred in Dublin. The death referred to enteric fever was recorded in Dublin, and the fatal case of scarlet fever occurred in Belfast. The deaths in the 22 towns referred to diseases of the respiratory system, which had declined in the five preceding weeks from 141 to 100, further fell last week to 90. Of the 389 deaths from all causes last week, 105, or 27 per cent., were recorded in public institutions. The causes of 13, or 3·3 per cent.,

## VITAL STATISTICS IN LONDON DURING FEBRUARY, 1911.

(*Specially compiled for* THE LANCET.)

* Including membranous croup. † The death-rates are corrected for variations in sex- and age-constitution of the populations of the several boroughs, the population of England and Wales being taken as the standard. ‡ Deaths from "typhus fever" and "other continued fevers" are not now distinguished in the Registrar-General's weekly returns; these two columns are therefore omitted from the Table.

of Military Hygiene and Epidemiology, the Parliamentary Committee of Hygiene, and so on. (What a pity they had not come down and seen about the conditions a couple of years before, when they might have been of use and prevented the epidemic!) When they did come it was thought that these frequent visitors did the patients no good but rather harm. One man, quite alarmed at having so many visitors, asked if he was really so very ill or why were so many people taking interest in him? The epidemic manifested great severity, and when symptoms of perforation did appear the patient was always too weak to endure an operation. The best treatment was complete rest, extreme cleanliness, and only liquid food. Convalescence was rarely protracted; patients being generally young recovered quickly, and had mostly ceased to discharge bacillus typhosus in stools or urine before the end of three months. In addition to the 317 cases of typical enteric fever there were a number of others suspected to be abortive attacks or slighter infections. They occurred especially as the main epidemic was decreasing. They had nearly all headache, the characteristic tongue, gurgling in the iliac fossa, and diarrhœa; generally they gave a marked Widal reaction very early, sometimes they showed rose spots and had a pyrexia lasting from one to three weeks. They were not sufficiently marked to be declared enteric fever, an important decision; if enteric they must be notified according to recent French law, but public opinion does not seem yet to be ripe for notification, in private cases at least, for that entails disinfection and other horrors. Ten orderlies fell sick in the Naval Hospital while nursing cases. Two of them died—possibly they were overworked, for the wards had 40 beds each and were nursed by two orderlies only.

The present most dangerous water-supply has cost France in the last 21 years the lives of 424 men from her army and navy, as well as some 140,000 days wasted in hospital. A horse costs some £20; what is a man worth to the State? Dr. Brunet, in the articles from which we have quoted, accepts a moderate £60 estimate and 2*s.* 6*d.* for each day in hospital, that makes £40,000, and when all the cost of sick leave, invalidings, pensions, and so on, are added in, he makes the total national expense £80,000 in 21 years. In addition, there is the loss to Cherbourg. Dr. Brunet cannot tell how many cases or deaths from enteric fever there have been among the civil population, but in March, 1909, when the service death-rate increased so much, the civil deaths were 128, 51 above the 77 of the same month in the preceding year. And the general death-rate per 1000 in 1904–1908 was in London 15·1, in Paris 17·7, but in Cherbourg 34. All this may appear rather an old story as well as a terrible one; the main point of narrating it in these columns is to accentuate my belief that matters have not been changed, and that the water-supply of Cherbourg is still a source of grave risk. We have shown here what disastrous results may follow when administrators and high officials neglect the considered and often repeated advice of responsible medical officers.

## MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

### *Cost of Sickness in Manchester.*

A FEW days ago Dr. J. Niven, the medical officer of health, read a striking paper at a meeting of the Manchester Statistical Society, on the cost of the sickness from which Manchester suffers. It may seem a cold-blooded method of treating the subject, but it is, of course, useful to estimate the cost of sickness in money. The suffering and distress cannot thus be calculated. Dr. Niven adopted the estimate that has been made that every man, woman, and child of the nation has an average value of £50. In the middle of 1909 the population of Manchester was 654,584, and on this estimate their value would be £32,729,200. Also, taking the number of deaths annually at 11,000, the value annually destroyed would be £550,000, "if the deaths were distributed in proportion to the numbers living at different ages," but instead of this being the case, death occurs chiefly at the ages when value was least or negative. It was estimated, also, that the annual expenditure in Manchester on sickness and funeral expenses would be £523,206. But this estimate is probably much too low, for the various sick-pay societies "were representative of thrift, and there was a large section of the community which was better off than their average members, while the expenditure on sickness in Manchester was very high." Dr. Niven gave the estimate of expenditure on sickness as follows: Public voluntary institutions, including nursing, £110,000; Poor-law expenditure on sickness, £70,000; private expenditure on sickness, £300,000; municipal sanitary expenditure, £116,000; with various other items, amounting in all to £741,000. The whole of this cost was not defrayed directly by the wage-earner, and he proposed to estimate the direct contribution at £500,000. He estimated the economic loss from phthisis alone at £500,000, but whether that estimate was correct or not it was evident that the annual loss to Manchester was enormous, "and that if the city, by expending £1,000,000, could effect its extinction the result would be cheaply arrived at." Dr. Niven said young people should be encouraged to play outdoor games. He had, too, a good word for military training in its effect on health, and said it would be a fine thing for discipline if the whole male population spent a year under training. It would involve loss, no doubt, but this would be least felt if the training were given at or about the age of 21, "at which age the greatest benefit would accrue." He said, moreover, that the mortality from phthisis in England and Wales fell at a more rapid rate from 1860 to 1900 than it had done recently, and that both in Germany and in England, "the steepest period of its fall coincided with a great access of commercial prosperity," when, of course, a family could the more easily be maintained in a well-nourished condition. This led to the question, he said, whether tuberculosis can be most cheaply prevented "by expending money in raising the nutrition of families in which tuberculosis had made its appearance, by housing consumptives in sanatoria, by other methods, or by a judicious combination of these methods."

### *Small-pox and Measles at Bury and Stalybridge.*

It is nearly seven years since Bury was visited with small-pox, but a serious outbreak has now occurred. About the beginning of the month Stalybridge has also suffered an outbreak of small-pox which has caused some anxiety. The sanitary authority is, however, making serious efforts to stamp out the disease. It is advising vaccination, while revaccination is carried out at the expense of the corporation. The Ashton guardians have prohibited visiting to the workhouse and hospital for the present, and the same plan has been adopted at the district infirmary. In addition to small-pox, Stalybridge has suffered from an epidemic of measles, and all the elementary schools in the borough are more or less seriously affected. It has spread rapidly during the last month, and the epidemic does not seem as yet exhausted. It may be remembered that in the last letter from Manchester it was a matter for congratulation that Stalybridge had a remarkably low death-rate. It may be feared that these visitations may affect it injuriously.

### *Hospital Saturday Fund.*

The annual meeting of the Manchester and Salford Saturday and Convalescent Homes Fund Incorporated was held recently in the town-hall, the Lord Mayor presiding. The total income for last year was £7166 6*s.* 10*d.*, a decrease of £275 on the previous year. The workmen's contributions showed a decrease of £161. The transfer of £250 from the reserve fund will, however, allow of the medical charities receiving £4400, the same amount as distributed last year. Hospital Saturday will this year fall on May 20th.

### *Gift of House and Land for Treatment of Phthisis.*

A very good excuse was made the other day by the Lord Mayor of Manchester for being a few minutes late at a meeting in the town hall. He said he had been receiving, on behalf of the city, the gift of a fine mansion and 40 acres of land in the country for a residential institution for children in the incipient stages of phthisis. The donor wished to hand the deeds over personally to the Lord Mayor. The site of the mansion, with a good deal of the land, is 500 feet above sea-level. There is ample meadow land for the keeping of cows, and the grounds are well adapted for outdoor shelter. The efforts which the education committee has made at Swinton in the treatment of physically defective children have been so successful that it is hoped that much benefit

will result in the case of the children treated somewhat similarly at Summerseat. It is proposed to commence the work with about 40 children, but with some extensions a larger number can be dealt with. Much good must result from Mr. Cuthbert C. Grundy's very generous gift.

*A School for Mothers.*

The annual meeting of the friends and supporters of the Manchester School for Mothers was held a week ago in the town-hall, the Lady Mayoress, Mrs. Behrens, presiding. It may seem strange that such a school should be needed, but as Mr. T. C. Horsfall remarked, "the manufacturing system, which had brought many of those present their wealth, had broken up family life and had deprived these women of the knowledge of how to deal with young children." This is a heavy indictment, but a true one, of our manufacturing system, so that, as he said further, an association like theirs was only doing its duty in supplying women "with the knowledge which the interests of their class had deprived them of." There are five branches in different parts of Manchester, and in the Ancoats branch, to take that as a sample, 468 women attended, among whom were many expectant mothers. They were advised as to how to prepare for the baby, and on its arrival they are advised as to its management. Weekly consultations are held, when every baby is weighed and when required it is seen by the doctor. Whether all this supervision may sometimes lessen the sense of parental responsibility need not here be considered, as this is a mere narrative; but there is no doubt that many an infant lives to be a year old when without this help and teaching it would have added to the mortality roll. At a year old it passes out of this school, and now the "Santa Fina Cripple Society" has agreed to supervise all children sent by the School for Mothers, and to continue their care till they are five years old, when they come under the inspection of the school medical officer. Dr. H. R. Hutton said that the object of the school was to try "to reduce the appalling death-rate in the congested districts of Manchester," largely due to the deaths of small infants. Mrs. Behrens commended the work of the school, to which she said all should subscribe.

March 18th.

## BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

*Hospital Saturday Fund.*

THE annual meeting of subscribers to this fund was held on March 13th under the presidency of the Lord Mayor. The report stated that the annual collection for last year amounted to £20,375, which is £686 in excess of the previous year. The number of contributing firms was 2188. In October £10,000 were voted for distribution among the medical institutions of the city. The work of the convalescent homes supported by them increased each year. In 1910 there were 1230 men at Tyn-y-Coed, near Llandudno, and 1388 women at Marle Hall, near Llanrhos. At Red House, Great Barr, the home for children, 615 children and 110 women were admitted. The total number of patients was 3343, an increase of 357 over the previous year. Good progress had been made with the Sir William Cook memorial scheme, and when the new home for consumptives at Romsley Hill was completed it would be handed over to the fund to be managed and maintained by the committee.

*Treatment of Consumptive Children.*

The success of the Salterley Grange and Yardley Road Sanatorium for Consumptives has raised the question whether similar provision should not be made by the health committee for consumptive children. At present there is no municipal or other institution where these children can be treated free. At a meeting of the city council the chairman of the health committee stated that they were prepared to undertake the treatment of such children if it were the wish of the council, and a subcommittee has been appointed to prepare a scheme. There has been much correspondence in the newspapers urging the importance of the subject. The primary duty of a health committee is, of course, the prevention of disease, and since children appear rarely to suffer from chronic phthisis and are not centres of infection in the same way as the adult consumptive it becomes a debatable question as to how far the municipal authorities are justified in treating other tuberculous conditions. If a sanatorium be limited to cases of pulmonary tuberculosis in children, then undoubtedly many cases of pulmonary disease would be admitted of a non-tuberculous nature, so great is the difficulty of distinguishing between these conditions. The health committee's scheme will therefore be awaited with much interest.

March 21st.

## WALES.

(FROM OUR OWN CORRESPONDENTS.)

*Cardiff Milk-Supply.*

COMPLAINTS are constantly being made by the inhabitants of Cardiff with regard to the quality of the milk-supply of the town. A suggestion has been made that the corporation should make arrangements for the examination of any sample of milk submitted by a householder. It is admitted that no action could be taken against the milk vendor in the event of the report of the examination being unsatisfactory, but it is contended that a knowledge of the poor supplies would be obtained and official samples could then be collected. At a recent meeting of the health committee the medical officer of health, Dr. E. Walford, stated that by arrangement with the South Wales and Monmouthshire University College and the Board of Agriculture and Fisheries, dairymen, farmers, and cowkeepers generally could have milk examined for a fee of 6*d.*, but that other persons would have to pay a fee to the public analyst of 10*s.* 6*d.* A subcommittee of the health committee has been appointed to consider the practicability of carrying out more frequent examinations.

*Glanders among Monmouthshire Pit Horses.*

In consequence of an outbreak of glanders among the horses in one of the collieries in Ebbw Vale which occurred last year[1] and which it was said had been the cause of the disease in several men, a departmental committee was appointed to consider what steps could be taken to deal with such outbreaks in the future. An Order has now been made by the Board of Agriculture and Fisheries empowering the Monmouthshire County Council to make regulations, applicable to any part of the county, for prohibiting the sale or disposal or removal from colliery premises of any horse, ass, or mule which has been used about the colliery, and prohibiting the burial or destruction of the carcass of any of these animals except under certificate given by an inspector, unless a reasonable opportunity has been given to the county council to ascertain by the mallein test or in some other way whether the animal was affected with glanders. The Order further enables the county council to prescribe the form of notice that shall be given of the intended sale, removal, or burial of one of the animals named.

*Aberystwith Health Report.*

The medical officer of health of the borough of Aberystwith, Dr. A. Thomas, states in his annual report that the birth-rate in 1910 was only 15·7 per 1000 of the total population, the death-rate from all causes 13·2 per 1000, and the infantile mortality-rate equal to 95 per 1000 births. The phthisis death-rate was 1·1 per 1000.

*Tregaron Health Report.*

The vital statistics relating to the rural district of Tregaron, in Cardiganshire, are in striking contrast to those of Aberystwith. In his report for 1910 Dr. Evan Lloyd states that the birth-rate was 16·7 per 1000 of the population, the death-rate from all causes 17·9 per 1000, the infantile mortality rate equal to 120 per 1000 births, and the death-rate from phthisis 3·2 per 1000. These death-rates are considerably higher than those which prevailed in the rural districts of England and Wales generally, and it is impossible not to connect them with the very unsatisfactory administration of the Public Health Acts which appears to prevail in Tregaron. Nearly four years ago Dr. E. P. Manby, after an inspection of the district on behalf of the Local Government Board, pointed out the direction which improvements should take, but little notice seems to have been taken of his suggestions. The inspector of nuisances is employed only three

[1] THE LANCET, August 13th, 1910, p. 517.

days in each week, and in view of the insanitary state of the district, where there is a population of nearly 8000 persons, the Local Government Board advised the appointment of an official devoting his whole time to his duties at an adequate salary. The district council refuses to accept this advice, notwithstanding the fact that the Board threatens to withhold its sanction to an appointment at an inadequate salary. The most urgent requirement of the district is a proper water-supply in the village of Tregaron, where there is a population of 750 persons. The existing supply is from wells, and when some of them are cleaned out periodically there is stated to be found a large deposit of offensive material, not unlike that accumulating in street gullies. Dr. Lloyd points out in his report that the lack of a proper water-supply is detrimental to the best interests of the village, for visitors naturally keep away from it, and the erection of new houses is prevented.

March 20th.

## SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

*Association of School Medical Officers.*

AN Association of School Medical Officers for Scotland has recently been formed. The first meeting is to be held on Saturday, April 8th, at 11.30 A.M., in the offices of the Govan Parish School Board, 151, Bath-street, Glasgow. All medical officers connected with schools in Scotland are invited to be present. The first president is Dr. Ernest T. Roberts, principal medical officer to the Glasgow School Board, and the honorary secretary is Dr. J. King Patrick, County Buildings, Ayr.

*Analysis of Food in Glasgow.*

It is evident, according to the annual report on the operations of the analyst's department in Glasgow, that the department has been very useful, both for purely analytical work and for the purpose of scientific investigation. The number of samples examined exceeds that of any previous year, no fewer than 3646 being dealt with. Dealing with the analysis of samples received under the Food and Drugs Acts, the report says that, defective and cumbersome as these Acts undoubtedly are, yet their strict enforcement provides a valuable protection against the adulteration of the food of the people, nowadays scientifically conceived and carried out. Of the 777 official samples received, 105 were certified as adulterated, whilst 33 were reported against as being of doubtful or suspicious quality. Regarding sweet milk, it is stated that much controversy has taken place over the Sale of Milk Regulations (1901) Act. The point under discussion is the fat limit, which is 3 per cent. On Nov. 15th, 1909, the first batch of samples, 60 in number, was taken at the different railway termini in Glasgow, and in only one was the percentage below 3. The sample contained 2·9 per cent. of cream, but 15 per cent. of added water, therefore the percentage of fat in the original milk was well above 3. During the year 237 samples of butter were submitted, 17 of which were certified as containing foreign fat in amount ranging from 16 per cent. to 89·5 per cent., whilst the percentage of water in one sample was above the statutory limit—namely, 19 per cent. The number certified as adulterated was 19, which is equivalent to 7·6 per cent., compared with 27·4 for the previous year. Amongst the miscellaneous samples was a packet of smoking mixture and a wooden pipe received by the police. The smoking mixture, which was said to be exposed for sale and retailed to children in the city, consisted of chopped-up dried leaves and flowers of the common coltsfoot. It has been left to the medical officer of health to decide whether the smoking of the herb by children is likely to produce any injurious effect.

*Paisley and the Home Treatment of Phthisis.*

The medical officer of health of Paisley has submitted a report to Paisley town council dealing with the proposal recently put forward for the home treatment of phthisis. He points out that the burgh of Rutherglen has adopted a "scheme" to encourage the securing by the householder of an extra apartment for the sole use of the patient. He suggests that in Paisley, where cases are brought to light in which owing to the number of young children and lack of proper accommodation proper precautions for the prevention of infection are difficult to attain, in cases of necessity the local authority might, in the event of the householder securing a house with an extra room for the sole use of the patient, pay the difference of rent between the smaller and the larger house. The town council, on the strength of this report, has appointed a committee to confer with the trustees of the Clark Fund, which provides a grant of 5*s.* weekly to a number of afflicted persons in Paisley.

*Milne Treatment of Scarlet Fever.*

At a meeting held last week of the Renfrew and Clydebank Hospital Board a letter was read from the Local Government Board with regard to the appointment of a nurse by the Clydebank Town Council to carry out the Dr. Milne treatment of scarlet fever. The communication stated that the Board, while having no objection to the rubbing of children with eucalyptus oil as a means of preventing infection, could not regard it as a substitute for hospital treatment. The Board indeed could not regard the treatment as obviating the need of the hospital.

March 21st.

## IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

*Work of the Dublin Sanitary Association.*

THE Dublin Sanitary Association is a voluntary society composed of persons interested in matters concerning the health of Dublin and its neighbourhood. At present it has a membership of 112 members. In spite of this meagre support from the public the council of the association undertakes courageously a large amount of work for the good of the community. The annual report of the year's work published last week touches on many subjects of prime importance. The council remarks that the condition of many of the primary schools, not only in Dublin but in many parts of Ireland, is so insanitary as to be a menace to public health. Especially is there a great need for proper medical inspection. The Commissioners of National Education have agreed that additional funds for the erection or improvements of school-houses are urgently necessary, and have declared that they would welcome similar provisions for medical inspection to those in force in England, but repeated applications to the Treasury have been without avail. Having noticed that an antivaccination crusade was being carried on in County Wexford, the council took steps, by correspondence in the newspapers and otherwise, to meet the arguments of the antivaccinationists. It has drawn attention also to a peculiar regulation of the Post-Office authorities regarding the outbreak of infective disease in the households of its employees. In the case of scarlet fever, small-pox, typhus fever, or epidemic cholera breaking out in the residence of a Post-Office servant he is to absent himself from duty, and report to the postmaster. In the case, however, of diphtheria, cerebro-spinal meningitis, measles, or enteric fever, he is not to absent himself, but is to report the circumstances to the postmaster. In either case the postmaster is to report to the chief medical officer in London, who is to decide what steps are to be taken. The council does not see any justification for placing diphtheria and measles in a different category from scarlet fever and cholera, and, moreover, thinks that reporting to the chief medical officer in London causes unnecessary delay. That the council keeps a close eye to neglect on the part of the sanitary authorities of the city is shown by the list of matters in which it was in correspondence with the cleansing committee of the Dublin corporation, viz.: the keeping of house dustbins in better repair, the repairing of the dust carts at present in use, the watering of the streets in front of the sweeping machines, the interference with the contents of the dustbins, the sweeping of the footways, and the overloading of manure carts and consequent scattering of the contents about the streets.

*Royal Victoria Eye and Ear Hospital, Dublin.*

The annual report of the Royal Victoria Eye and Ear Hospital presented last week showed that during the past year 1428 patients were admitted, the average daily number of beds occupied being 77·87. In the out-patient department 10,132 persons were attended. The hospital has a large adverse balance at the bank.

*The Vacant Inspectorship of Lunacy.*

Dr. W. R. Dawson, medical superintendent, Farnham House, Dublin, has been appointed by His Excellency the Lord Lieutenant to the vacant post of Inspector of Lunatic Asylums in Ireland.

*Belfast and Midwives Legislation.*

The inclusion in a Belfast corporation omnibus Bill at present before Parliament of clauses governing the practice of midwifery in Belfast is likely to cause perturbation among those who are anxious to obtain a Midwives Bill for Ireland as a whole. The Belfast Bill proposes to establish a Belfast Midwives Board with powers for the city of Belfast very similar to those possessed by the Central Midwives Board for England. It would establish a roll of midwives, and practice by others than those on the roll would be prohibited. The drafting of the Bill is far from clear, but it would appear that the Board would appoint examiners and conduct examinations of persons applying for admission to the roll. The Dublin School of Midwifery is likely to offer strenuous opposition to any attempt to deal with the midwives question as a purely local matter. It is, moreover, pointed out that it is not so much in the large cities as in country districts that harm is done by ignorant and untrained "handy women."

*Double Tenement Houses in Belfast.*

Mr. Peter Kerr-Smiley, M.P., has given notice that after the second reading of the Belfast Corporation Bill he will move:—

That it be an instruction to the committee which will in due course consider the Bill to insert a clause compelling owners of tenement houses in Belfast to provide adequate separate sanitary conveniences for each occupier.

On page 78 of the report of the Belfast Health Commission it is said: "A serious blot in Belfast housing is that in certain cases (streets are given) the houses which were built for one family are now double-tenanted—one family occupying the ground floor and a separate family the upper floor. In these cases the tenant of the upper floor has no access to the yard and conveniences except through the rooms of the lower tenant, and when, as frequently happens, the lower tenant is at work and has locked his rooms, the upper tenant may have for long periods no access at all to the conveniences in the daytime, while at night such access must be almost impossible. This condition of things is in all respects most unsatisfactory, and leads to fæcal matter being stored in the upper living rooms until an opportunity occurs to carry it to the yard. On the ground that the upper tenancies have in effect no sanitary accommodation, these double tenancies should be sternly abolished, or the provision of an external stairway from the upper rooms to the yard should be insisted on"; and on p. 101 of the same report the Commissioners recommend: "Double tenancy of houses should be prohibited save where suitable water-closet accommodation is provided for each portion of the house let independently."

*Down County Infirmary.*

From the report just issued it appears that during the year 1910 the number of patients admitted was 576, making, with those in hospital on Jan. 1st, 1910, a total of 621 cases treated during the year. 1254 patients attended the extern department and 49 tuberculous patients were admitted to the sanatorium. Both hospitals have been repainted and repaired, and a steam steriliser and destructor have been erected. Financially the total income was £2444 4*s.* 5*d.* and the expenditure £2308 17*s.* 3*d.*, leaving a balance of £135 7*s.* 2*d.* to credit.

March 21st.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

*Reconstitution of the Institute of Medical Jurisprudence.*

MEDICO-LEGAL investigations have been carried on since 1864 in Paris in a building in the department of the Prefecture of Police, situated at the extreme point of the *Cité*, and well known under the name of the Morgue. For some years past its condition has been deplorable; the building is too small, the freezing apparatus for the subjects is insufficient, and the post-mortem chambers, which are ill-lighted, very cold, and damp, are both inconvenient and unhealthy. There is little doubt that it was in the Morgue that Dr. Brouardel and Dr. Laye, contracted the germs of tuberculosis. At the creation, five years ago, of the Institute of Medical Jurisprudence with the diploma of *Médecin légiste*, the Faculty of Medicine naturally utilised this edifice, frequented at the present time by numerous students as well as by French and foreign medical men who pursue their studies in these lugubrious surroundings. For the last 30 years the State and the Ville de Paris have been negotiating the transfer and the reconstruction of the Morgue, each party endeavouring to lay the heavier share of the expense (estimated at £40,000) on the shoulders of the other. They have finally come to an agreement, the expenses to be equally shared between the two parties, and a new institute of legal medicine is to be raised in the Place Mazas, on the site where the prison, now demolished, stood. At the Chamber of Deputies M. Escudier, who was commissioned to report on this scheme, has recommended its adoption, and communicated the chief features of the organisation of the future institute. The establishment will comprise three distinct services—viz., (1) administration: the reception and recognition of corpses, &c., arranged in an infinitely more suitable manner than in the dingy and doubtful receptacles at the present Morgue; (2) post-mortem service and judicial operations, consisting of three necropsy chambers and a laboratory for medico-legal examinations; and (3) service for the study of medical jurisprudence, including an amphitheatre with seats for 200 students, a laboratory of toxicology, receptacles for animals to be used for experimentation, a museum, and a library. M. Escudier adds that the institute will also comprise rooms which, with the permission of the Vice-Rector, may be granted to men of science and workers desirous of undertaking researches or making experiments.

*Transplantation of the Fibula.*

At a recent meeting of the Society of Paris Surgeons M. Euguier showed a man who had suffered from osteo-sarcoma which had necessitated resection of 9 centimetres of his left humeral diaphysis. M. Euguier removed *en bloc* the bone, the tumour, and the brachialis anticus and triceps muscles which were affected, but the nerves and vessels supplying the arm were preserved. He then replaced the loss of substance by introducing into the medullary cavities of the divided portions of the humerus a piece of the right fibula 13 centimetres long and having its ends pointed. The fixation of the transplanted bone in its new position was assured by some taps with a mallet on the olecranon. In nine months after the operation the patient had good use of the arm and resumed his previous occupation of sawing timber in a forest. The upper end of the transplanted portion of the fibula united firmly with the humerus, but at its lower end there was a false joint between it and the inferior epiphysis of the humerus. The tumour was a cystic osteo-sarcoma with myeloplasia in the periosteum of the anterior lower half of the humeral diaphysis.

*Pericardotomy.*

Pericardotomy was recently performed by Dr. Jacob at the Val de Grâce Hospital, and an account of the case was communicated by M. Bochard at a meeting of the Surgical Society held on Feb. 22nd. The patient was a man, aged 23 years, who was admitted in a condition approaching asphyxia and presented signs of pericardial effusion which was probably of tuberculous origin. Two successive punctures having been without effect, Dr. Jacob resected the fifth costal cartilage under local anæsthesia, and incised the pericardium which was found to be somewhat adherent to the heart. On these adhesions being broken up by the finger a considerable amount of serous liquid escaped, after which the soft parts were brought together without suturing the pericardium and without drainage. The patient immediately experienced great relief and made a gradual recovery. The subsequent formation of two pleuritic patches as well as of obvious lesions in the pulmonary apices explained the etiology of the pericardial effusion.

March 20th.

THE SMALL-POX EPIDEMIC IN LONDON.—March 21st was the ninth successive day on which no case of small-pox was notified to the Metropolitan Asylums Board. Chicken-pox has been made a notifiable disease for a period of three months from March 22nd.

## BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

*Cholera Prospects.*

ALTHOUGH the Hungarian newspapers are jubilant over the announcement that cholera has disappeared from the country, sanitarians are not without misgivings as to what may happen when the warm season returns. This epidemic, now fortunately concluded, commenced at the end of last summer and continued until the end of January, 1911, with an average of one or two fresh cases notified every day during that month. Cases occurred in about 100 villages, in several towns, and even in the capital, Hungary presenting in this respect a great contrast to Austria, Germany, and France, where the disease obtained no permanent footing but was only represented by imported cases. In Hamburg about 18 years ago there was a disastrous epidemic which broke out in the harbour, but during the present cholera season there was only one case in Hamburg, the disease being prevented from spreading. It must be confessed that in these matters Hungary lags behind the western nations, and this defect is so well recognised here that the National Health Committee has communicated with the Minister of Public Health (who is also the Minister of Internal Affairs) recommending that the head of the hygienic section of the Ministry should proceed to Germany and make himself acquainted with the methods by which that country prevents the entrance of cholera by land across the Russian frontier or by the rivers coming from Russia. At the same time it deserves to be recorded that some good work was done in Hungary for the suppression of isolated outbreaks. This was the case at Mohacs, the first place invaded by the disease in this country. This town lies on both banks of the Danube, the water of which river was bacteriologically proved to be polluted with cholera bacilli. The first requisite was a supply of wholesome drinking water, and the use of water from the Danube was strictly forbidden. All the wells in the town were examined, and those which were not sufficiently clean were closed. Civilian health officers were sent into every district of the town, always accompanied by soldiers armed with rifles, to search for patients, because from the point of view of the spread of the disease a hidden cholera patient was of more importance than even ten fatal cases. This investigation conducted under the protection of an armed force had a good result. For while up to that time only fatal cases had been notified, and cholera patients were, so to say, not seen, on the first day of the systematic search a dozen patients were conveyed to the improvised cholera hospital. A fairly good ambulance vehicle was also provided for their removal in lieu of the common carts, which had been used for this purpose, and from which the vomit of the cholera patients fell on the road. By an exhibition of kindness and tact the health officers succeeded not only in calming the public alarm but also in convincing the people of the benefits of isolating patients. Eventually the people allowed their sick relatives to be carried to the hospitals, seeing that these institutions supplied them with clean beds and good food. The families of the cholera patients were also provided for by the Red Cross Society, and artisans who were unable to earn their living on account of the quarantine received one or two kronen daily as subsistence money. The healthy occupants of infected houses were isolated for five days. The municipal medical officers also went personally from house to house, searching for patients and impressing on the people the necessity of isolation, with the result that whereas formerly medical men were threatened with death if they dared to remove patients to the hospitals, such removals were now accomplished without resistance or difficulty. This energetic interference had the effect of stopping the cholera in five days, and in the ensuing five weeks there occurred only five sporadic cases. In Bata, a town in a rural district also on the banks of the Danube, where in one single day 30 cases were notified with 15 deaths, the board went to work in the same way as in Mohacs, the result being that in seven days there were no fresh cases. It must be said that these successful applications of hygienic measures were exceptional instances of their kind, and foci of cholera still remained scattered about the country. According to Dr. Schächter, chief editor of the *Gyógyászat* (*Therapeutics*), one reason of this was that the orders of the Central Board located in Budapest all came late. The Central Board did not authorise independent action by the local boards, which, therefore, had to write to the Ministry for instructions in every matter of detail, and this circumlocution caused much delay.

*Incident at a Royal Hospital Visit.*

His Majesty Emperor Francis Joseph recently paid a visit to the General Hospital, where he saw a patient, a Polish Jew, who, the chief physician said, was suffering from the same disease to which an American railway millionaire had fallen a victim. The patient thereupon remarked to His Majesty: "Alas! such is my luck. I wanted his money and I got his illness."

March 13th.

## UNITED STATES OF AMERICA.

(FROM OUR OWN CORRESPONDENTS.)

*Teaching the Importance of the Teeth.*

THERE is a feeling among the dentists of the United States that dentistry should be made definitely a branch of the medical profession; in other words, that students intending to practise dentistry should be made to take a full course in medicine first. There is little doubt that there will soon be free dental clinics established in all the public schools of New York. At present the teeth of all pupils are examined, as well as their vision and hearing, and if defects are found the child is given a letter to his parents advising the importance of having them remedied. At the Academy of Medicine recently a public lecture on the teeth was given under the auspices of the Health Committee of the American Medical Profession, and was largely attended. The lecturer pointed out the far-reaching results on the ribs and other portions of the human frame of dentures which had been allowed to persist in distorted shape; he also foretold the early disappearance of the wisdom teeth from members of the human race.

*A New Infant Asylum.—New Ward in Cancer Hospital.*

Governor Dix, of the State of New York, dedicated the new Hebrew Infant Asylum at Aqueduct-avenue and Kingsbridge-road on Feb. 23rd. It is a five-storey red brick structure, with accommodation for 450 children, and cost £90,000.—A new ward for incurables in the New York Skin and Cancer Hospital was opened on Feb. 17th. Malignant cases, which other institutions will not receive, will be admitted to this ward. The research laboratory is being extensively equipped with apparatus obtained mainly in Europe.

*The Latest Move by Anti-vivisectionists.*

A Bill has been introduced into the New York State Legislature "to prevent cruelty by conferring upon the board of regents of the University of the State of New York the power of supervision of experiments upon living animals." No experiments are to be permitted unless for knowledge useful in saving or prolonging life, and no experiment is to be permitted to demonstrate known facts. Supervisors of animal experimentation are to be appointed upon certification from humane societies. They are to have authority to enter any place licensed for vivisection. Annual reports must be made by experimenters of the number of experiments, animals used, anæsthetics, if any, and results. Anyone performing or assisting in vivisection in violation of the Act is punishable by one year's imprisonment. The object of all such legislation, apparently fair on the face of it, is to permit the entrance of lay inspectors to the laboratories of experimental physiology, whose reports, couched in unscientific and uncomprehending language, will probably cause such a wave of popular hysteria as to close up the laboratories for ever.

*An Arrest for Witchcraft.*

At Reading, Pa, a quack has been arrested on the charge of practising witchcraft as a "hex doctor." His patient was a young child suffering from marasmus. When his medicines produced no improvement, he informed the mother that the child was under a spell and that he was about to make an incantation that would break every bone in the body of the malevolent person who had cast the spell. His subsequent performances threw the child's mother into acute hysteria,

whereupon her husband brought about the quack's arrest on the charge aforesaid.

*Continued Opium Seizures.*

A few weeks' activity on the part of the Federal officials has resulted in the seizure of four tons of smuggled opium of a total value of over £20,000. It was found that practically all the opium was smuggled in from Canada, Mexico, or from the East through the Puget Sound territory. The seized opium will be sold by auction to recognised wholesale druggists.

*Diphtheria in Baltimore.*

At the presesent time diphtheria is very prevalent in Baltimore. It first showed itself in Johns Hopkins Hospital, and quickly spread amongst patients, nurses, physicians, and students. On Feb. 25th Dr. J. Whitridge Williams, dean of the Johns Hopkins medical school, ordered the school to be closed until further notice. Since then most of the hospitals in Baltimore have been closed in order to protect their patients. The disease has spread considerably in the city, and a large number of Johns Hopkins medical students are quarantined in their own homes.

*Typhoid Fever Epidemic in Erie, Pennsylvania.*

In Erie, Pa., a town on the Canadian border, a typhoid fever epidemic of great virulence is raging. Ten deaths from the disease were reported during the 24 hours ending March 1st. It is estimated that taking into consideration the number of cases in Erie itself and its suburbs and in the small towns across the Canadian border there are 1000 cases of typhoid fever in the district. The cause has not been yet determined, but the outbreak is thought to be due to typhoid-infected sewage which has been allowed to flow untreated into Lake Erie in the vicinity of the town of Erie. The question of the pollution of rivers, streams, and lakes is now receiving the attention of both Federal and State authorities in this country; especially is the question of the pollution of the Great Lakes being discussed by health authorities. Surgeon-General Walter Wyman, of the Public Health and Marine Hospital Service, is of the opinion that the national Government should intervene. and that the careless and criminal pollution of the Great Lakes which is now going on should, in the interests of the community at large, be stopped as soon as possible. The stumbling-block to the enactment of legislation to this effect is as to how the State and Federal laws bearing on the point are to be interpreted—that is to say, whether by virtue of the constitution the national Government has the right to interfere. This point is likely to be settled in a short time.

*Appointment of Dr. W. Smith as Superintendent of Johns Hopkins Hospital.*

Dr. Winford H. Smith, who for the past two years has filled the position of superintendent of Bellevue Hospital, New York, has resigned to accept a similar post at the Johns Hopkins Hospital, Baltimore.

March 11th.

## NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

*The Smoke Nuisance at Calcutta.*

THE health committee of the corporation will shortly consider the recommendations of the Bengal Smoke Nuisance Commission regarding the modification of the existing Act. In a letter from the President of the Commission it is stated that a great nuisance arises at night from the open flames of oil lamps, 20,000 or 30,000 of these being in various shops and small factories in the town and suburbs. It is calculated that the smoke is equal to about 200 ordinary factory chimneys. The amendment of the Act to prohibit the use of such lamps is suggested, as the smoke is of high gravity and a fruitful source of throat and lung complaints.

*Cocaine Smuggling.*

During recent months the Excise authorities have engaged in a vigorous campaign among foreign seamen coming to Bombay and have succeeded in seizing large quantities of cocaine before it could be passed on to those on shore who exploit the traffic. But the "importers" will risk punishment in the hope of landing a consignment which need not be large in bulk or original value to ensure an amazing profit. The authorities in Bombay are aware that the European seamen in question have European confederates in the city. It may suggest itself to those concerned that if the shipmasters are also fined when contraband is discovered on board their vessels, the fact that the fines are distributable and recoverable from all members of the crew in rateable proportions to their wages will have the effect of providing the authorities with many valuable allies on board the ship. This is done on the other side of India, and that the method has been most satisfactory in its working.

*Plague Measures in Moulmein.*

Captain W. F. Brayne, I.M.S., officer on general plague duty in Burma, in his recent inspection note on Moulmein, makes some interesting remarks. He deals with the failure of the plague measures and condemns the procedure. The lodging-house by-laws were used, not as a means of keeping the houses sanitary, but for the collection of revenue in the form of a lodging tax. Captain Brayne's opinion is that plague work in Moulmein in the past has been of no value, and that the money spent has been wasted. He recommends several measures, amongst them the appointment of a European commissioned officer on special plague duty for Moulmein only and the formation of a sanitary committee. As the former will entail expenditure which the Government is not likely to sanction, he is in favour of abolishing plague measures altogether and leaving the treatment of plague to the civil surgeon, as he deals with other infectious diseases.

*The Spread of Cholera.*

Lieutenant-Colonel Leonard Rogers, I.M.S., delivered an interesting address on cholera at a meeting of the Asiatic Society recently held in Calcutta. He remarked upon ancient references to a disease which may well have been cholera, and referred to the terrible epidemics that have occurred in the past hundred years both in Asia and Europe. He said that the epidemic in Russia in 1910 caused over 90,000 deaths up to the end of last September. The outbreak in Italy resulted in 1000 deaths in Naples district during that month, while the disease also appeared in Portugal, Turkey, and Madeira. He went on to say that numerous cases had also occurred in Eastern Germany, so that a large portion of Europe had now been invaded. The histories of the earlier epidemics always showed a marked lull during the winter months, and it was just possible that especially severe cold might destroy the infection, but unfortunately all the facts pointed to a still further spread of the disease, especially in Southern Europe, during 1911, the position being more serious than at any period since the 1883 outbreak in Egypt and the South of Europe. With regard to the prospects in England there was little ground for alarm, as the English inspection system had been uniformly very successful in preventing any spread from imported cases, while the excellent water-supplies of English towns had robbed the disease of its principal terrors. The same remark applied to a considerable extent to Germany and France, but it was to be feared that the more southern parts of Europe still frequently presented favourable opportunities for the spread of cholera, owing to sanitation being less advanced in their towns.

*The late Surgeon-Major R. E. Wrafter.*

I regret to announce the death of a veteran Indian officer, Surgeon-Major R. E. Wrafter, who died in Dehra Dun on Jan. 23rd in the seventy-eighth year of his age. Major Wrafter entered the late Bengal (H.E.I.C.'s) Medical Service in the year 1848, just in time to serve through the Punjab campaign of 1848–49, in the course of which he was present in the affair of Ramnuggar, the passage of the Chenab river, and the battles of Sadoolapur, Chillianwala, and Guzerat. At the outbreak of the Mutiny he was at Meerut, and subsequently took part in the engagements of the Hindun (May 30th and 31st) and of Budlu-ka-Sarai (June 8th). He was present throughout the siege and capture of Delhi, at the action of Nudjuffghar on August 25th, 1857, at the siege and capture of Lucknow, and was on service till the very end of the long struggle, being engaged throughout the campaign in Rohilkhand, including the attack on Fort Rooya, the action at Allygunj in Oudh, the capture of Bareilly, and the pursuit of the rebels at Shahjehanpur and Mohumdee. He entered civil employ in the year 1864, and was civil surgeon at several stations in the United Provinces and the Punjab. After 40 years' service Major

Wrafter retired and in 1888 settled at Dehra Dun. His unfailing kindness and sympathetic disposition endeared him to all with whom he came into contact.

*United Provinces Exhibition, Allahabad.*

It is impossible to give a detailed account of the many exhibits, but at the same time it is worthy of note to mention the enterprise of some British firms. It can safely be said that Messrs. Down Bros'. exhibit was one of the best. It showed a collection of surgical and other appliances of great value, and besides this their stall was highly instructive, especially to Indians who visited this exhibition. They put in place a complete surgical ward, an anæsthetising chamber, an operating theatre, a sterilising room—comprising every piece of necessary furniture and appliance for a complete operation in an up-to-date hospital. Besides operating tables and aseptic glass tables, there were diagnostic finger-stalls, clamps, forceps, cystoscopes, aero-urethroscopes, and every surgical contrivance. Messrs. Burroughs, Wellcome, and Co. had a most interesting stall showing their well-known tabloids and various therapeutic sera, besides tinctures, &c. Of particular interest to the tropics were their samples of tubes containing quinine hydrochloride in 4-grain treatments. Jeyes' Sanitary Compounds Co., Limited, were exhibiting their disinfectants. Pearson's Antiseptic Co. likewise were exhibiting the products which bear their name. On behalf of Messrs. Watson and Sons, London, Messrs. Smith, Stanistreet, and Co., of Calcutta, were exhibiting a very complete X ray outfit. This Calcutta firm made a very excellent show. The Empire Engineering Co., of Cawnpore, showed a most interesting lot of sanitary appliances of value in Indian municipalities. Lastly, *Indian Public Health*, the only sanitary journal in the East, had a stall. The exhibition was a great success.

Feb. 24th.

# Obituary.

## ANDREW SMART, M.D. EDIN., LL.D., F.R.C.P. EDIN.,

CONSULTING PHYSICIAN, ROYAL INFIRMARY, EDINBURGH, ETC.

Dr. Andrew Smart, whose death on March 8th at the residence of his son, 78, Bertram-road, Hendon, N.W., was noted in our issue of last week, was in his eighty-seventh year. He was the youngest son of an English gentleman who owned large properties in Jamaica. His mother was a Miss Christie, a member of a well-known Stirlingshire family. He took his degree as M.D. at the University of Edinburgh in 1862, and in 1865 was elected a Fellow of the Royal College of Physicians of Edinburgh. He was appointed assistant physician to the Edinburgh Royal Infirmary in 1880, becoming in 1900 senior ordinary physician to that institution, the appointment being renewed for a term of five years 12 months later. He retired in 1906 and was appointed a consulting physician to the infirmary. He was at one time assistant to the professor of the practice of medicine at the University of Edinburgh, and to the professor of clinical medicine, and was a lecturer and examiner in clinical medicine and therapeutics at the Royal Infirmary, besides holding many minor appointments. He was an Ext. Memb. of the Royal Medical Society of Edinburgh, and an honorary member of the New York State Agricultural Society. St. Andrews University conferred on him its honorary degree of LL.D. Dr. Smart is said to have been the first to discover the presence of micro-organisms in living tissue, the discovery being made in connexion with his work on rinderpest in 1865, the results of which are embodied in his reports on rinderpest to the Lord Provost, magistrates, and town council of Edinburgh. He there showed that freshly drawn rinderpest blood presented under a high magnifying power chains of minute bodies lying between the blood corpuscles and completely surrounding them and the other histological elements. These chain-like structures, in virtue of their prodigious numerical superiority, are seen to occupy the entire microscopical field. It is said that Dr. Smart's delineation of the blood in rinderpest, with the accompanying reports, originated the belief in the germ origin of disease and led to the earliest statement on record expressive of what is now understood as the "germ theory of disease." Dr. Smart's reports were translated into several continental tongues and attracted commendation from the leading pathologists, British and continental. His studies in anæmia appeared in THE LANCET of Feb. 18th and 25th, 1893. A little book by Dr. Smart, entitled "Germs, Dust, and Disease," is a republication of two lectures—the first on Preventable Disease, the second on Occupational Diseases—delivered by him to popular audiences. Both represented an advanced stage of thought at the time they were delivered, and much that was there laid down has already become, or is in process of becoming, generally adopted.

Dr. Smart is survived by a widow, four sons (one of whom is Dr. A. G. H. Smart of Kelantan, Federated Malay States), and two daughters.

## WILLIAM PALEY, M D. LOND., M.R.C.S. ENG., L.S.A., J.P.

THERE passed away on March 13th, at the residence of his son-in-law, Mr. Alfred Saunders, at Ealing, a worthy and highly respected representative of the older school of provincial consulting physicians, in the person of Dr. William Paley. Dr. Paley was in his 95th year, and had retired from practice since 1894. He was a son of the Rev. Edmund Paley, rector of Greatford, and consequently a grandson of the Rev. William Paley, Archdeacon of Carlisle and Prebendary of St. Paul's, widely known through his "Evidences of Christianity" and "Natural Religion." His eldest brother was Professor F. A. Paley, the distinguished classical scholar of Cambridge, and later of Stonyhurst. Dr. Paley was educated at Christ's Hospital, and received his medical training at the London Hospital. He took the L.S.A. in 1837 and became M.R.C.S. in 1839. In the early "forties" Dr. Paley went to Peterborough as house surgeon to the Infirmary and Dispensary. He soon decided, however, that his bent was for practice as a consulting physician rather than as a general practitioner. In 1842 he took the M.D. of London, and soon allied himself with Dr. Skrimshire, a well-known consultant in Peterborough, whom in 1846 he succeeded in the post of physician to the Infirmary, and the work done at Peterborough by himself, by his younger colleague and great friend, Dr. J. T. Walker, and by Dr. Walker's father, forms a remarkable feature in provincial medicine. He retained his official connexion with the Infirmary for 36 years. On resigning in 1882, Dr. Paley was appointed physician extraordinary, his post on the staff being then filled by his son, Dr. W. E. Paley. On the death of the latter in 1894, Dr. Paley retired altogether from practice. Dr. Paley's consulting practice covered a very large field—viz., the wide district surrounding the city of Peterborough and lying in the four counties of Northampton, Lincoln, Cambridge, and Huntingdon. He retained his mental and bodily vigour up to the last, having been a man of abstemious habits and devoted to active outdoor exercise—a fisherman, a keen sportsman, and an excellent shot. He was a man of strong religious convictions and an active worker in charitable and social movements. He was a justice of the peace for the Liberty of Peterborough, one of the first aldermen of the borough, and its third mayor, being elected to that office in 1877. Politically a Whig, he followed the leaders of the Liberal Unionist party when they allied themselves with the Conservatives in the "eighties." He was at one time president of the Cambridge and Huntingdon Branch of the British Medical Association. Dr. Paley married Miss Harriett Simpson, by whom he had four sons and two daughters, of whom the daughters alone survive their father.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Witthauer, oberarzt of the Deaconess Hospital in Halle. Dr. Otto Deasch, professor of histology and embryology, and at the time of his death dean of the medical faculty of the University of Gratz. Dr. Georg Kapsammer, physician to the Franz Josef Dispensary and to the Jubilee Hospital of the City of Vienna. His published monograph on the diagnosis of functional diseases of the kidney is held in high repute. Dr. L. Russ, professor of clinical medicine in the University of Jassy. Dr. A. Chavanne, formerly physician to the Lyons Hospital and Deputy for the Rhône. Dr. L. Orfila, professeur agrégé of the

Paris Faculty of Medicine. Dr. Aloysius O. J. Kelly, professor of pathological anatomy in the Woman's Medical College of Pennsylvania in Philadelphia and editor of the *American Journal of the Medical Sciences*. Dr. S. D. Hopkins, professor of the diseases of the nervous system in the Denver and Gross College of Medicine.

# Medical News.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following candidates have passed the primary part of the Fellowship examination:—

E. Connell; C. Cooper, L.R.C.P. & S. Irel.; H. A. S. Deane; T. W. Harley, M.B., B.Ch. Dub., Captain I.M.S.; A. Humphreys; J. C. Khambatta, M.B., B.Ch. Edin.; T. J. R. Maguire; and J. C. Sproule.

The following candidates have passed the final part of the examination and have been admitted Fellows of the College:—

L. L. Cassidy, M.B., B.Ch. Edin., and R. V. Slattery, M.B., B.Ch. R.U.I.

FOREIGN UNIVERSITY INTELLIGENCE.—*Bonn:* Dr. R. Cords has been recognised as *privat-docent* of Ophthalmology.—*Budapest:* Dr. K. Pellyesniczky has been appointed to the chair of Anatomy.—*Catania:* Dr. Giovanni De Gaetani of Palermo has been recognised as *privat-docent* of Medical Pathology.—*Frankfort:* It has for some time past been expected that this important town would be made the seat of a university, and several scientific institutes which would naturally form part of the equipment of a university have already been for some years in active operation. It is now announced that three faculties of the proposed university may be expected to be opened in 1914—viz., those of Medicine, Philosophy, and Law.—*Greifswald:* Dr. Lange, director of the Ear Clinic, who has been invited to accept the chair of Otology at Erlangen, has decided to remain.—*Lemberg:* Dr. J. St. Hornowski has been recognised as *privat-docent* of Pathological Anatomy.—*Prague (German University):* Dr. Alfred Kohn has been promoted to the Ordinary Professorship of Histology; Dr. Gottlieb Salus has been recognised as *privat-docent* of Hygiene.—*Vienna:* The vacancy in the "Third" Medical Clinic and Professorship caused by Dr. von Strümpel's retirement is to be filled by the appointment of Professor Sahli of Berne. The other names mentioned in connexion with this important appointment were Professor Chvostek of Vienna and Professor Ortner of Innsbruck. Dr. Hans Salzer has been recognised as *privat-docent* of Surgery.—*Zürich:* Dr. Otto Busse of Posen has been appointed to the chair of Pathological Anatomy in succession to Dr. M. B. Schmidt, who is going to Marburg.

ROYAL FREE HOSPITAL.—H.R.H. Princess Christian, the President of the hospital, who was accompanied by H.H. Princess Marie Louise, presided at the eighty-third annual court of governors of the Royal Free Hospital, which was held on March 15th. There was a large attendance of governors. In moving the adoption of the report, Mr. Chaplin referred to the lamented death of King Edward, who had been a patron of the hospital. After referring to the work of the hospital during the past year and to the improved financial position, he pointed out that owing to the great pressure made by the sick poor upon the resources of the charity it had been necessary from time to time to make structural alterations and additions to the buildings. At the present time the great need of the hospital was a new out-patient department and for this purpose it was absolutely essential to obtain additional land, all the available space being already fully occupied. Negotiations were in progress and it was hoped that the difficulty of obtaining the necessary land may be overcome in the near future. After referring to the increased cost of maintenance of the hospital, Mr. Chaplin stated that the financial anxiety of the committee had been greatly relieved by the generous legacy of £50,000 bequeathed by the late Mr. H. Silver, who had for nearly 40 years been an active member of the committee and weekly board of the hospital. Reference was made to the cordial relations of the hospital with the London School of Medicine for Women, and in conclusion Mr. Chaplin announced that after many years of service Mr. Conrad Thies, the secretary, was relinquishing his post, but it was hoped that he would continue in the future to give them the benefit of his long experience in hospital affairs by taking an active part in the administration of the hospital. The Bishop of Islington moved the appointment of the committee of management and treasurers. The usual votes of thanks closed the proceedings.

THE ORDER OF THE CROWN OF ITALY.—The King has given to the undermentioned His Majesty's Royal licence and authority to accept and wear the decoration of Officer of the Order of the Crown of Italy which has been conferred upon them by His Majesty the King of Italy, in recognition of valuable services rendered by them at the time of the earthquake at Messina in the year 1908: Michele Asphar, M.D., Sliema; Placido Biasini, M.D., Sliema; Salvatore Borg, M.D., Hamrun; Salvatore Ellul Grech, M.D., Valletta; Edgar Henry Ferro, M.D., Sliema; Paolo Grech, M.D., Birchircara; Francesco Jaccarini, M.D., Senglea; Salvatore Muscat, M.D., Balzan; Emmanuele Said, M.D., Valletta; Surgeon-Captain Robert Samut, King's Own Malta Regiment of Militia, Sliema; Giuseppe Wirth, M.D., Valletta; and Carol Zanghi, M.D., Floriana.

THE TUBERCULIN TREATMENT: BRIGHTON.—The Brighton town council at its meeting on March 16th adopted the recommendation of its sanitary committee with respect to the tuberculin treatment at the Brighton Sanatorium. Dr. Duncan Forbes, the medical officer of health, after a study of the results obtained in the German sanatoriums, introduced tuberculin treatment at Brighton, and the results have been satisfactory. Dr. Forbes says: "In most cases, in order to obtain a cure or lasting benefit, the tuberculin treatment has to be continued for at least one year. The result is that at present patients are discharged who are steadily improving under tuberculin treatment, but long before their cure is obtained. It would therefore seem necessary, in order that the benefits derived from our sanatorium treatment may be increased to a maximum, that discharged patients who have benefited from tuberculin treatment should return at intervals to the sanatorium for further injection with tuberculin." Dr. Forbes advised the extension of the sanatorium treatment, a suggestion readily agreed to. In April last a ward was opened at the sanatorium for cases of tuberculous joints. Six cases of spinal caries, 5 of hip disease, and 2 of knee-joint disease had been admitted, and 12 of these still remained in hospital.

UNIVERSITY OF LONDON: FACULTY OF MEDICINE.—A meeting of the Faculty was held at the University on March 18th. Dr. Norman Moore took the chair and the election of Dean for the remainder of the period 1910–12 was proceeded with. Professor Sidney Harris Cox Martin was proposed by Dr. W. P. Herringham and seconded by Mr. H. J. Waring. The proposition was put by the chairman and carried unanimously. Professor Martin then took the chair. The constitution of the Board of the Faculty was determined as follows: (*a*) The Dean of the Faculty (Professor S. H. C. Martin); (*b*) the secretary of the Faculty (Mr. H. J. Waring); (*c*) the members of the Faculty who are also members of the Senate (at present Sir William Allchin, Dr. H. A. Caley, Professor A. W. Crossley, Professor R. J. Godlee, Sir Alfred P. Gould, Mr. Leonard Hill, Dr. E. G. G. Little, Professor J. M. Thomson, Dr. J. Wade, and Dr. A. D. Waller); (*d*) the chairmen of the following boards of studies: preliminary medical studies (Professor F. Womack), intermediate medical studies (Dr. C. Addison), advanced medical studies (Sir Francis Champneys), dentistry (Sir Alfred P. Gould), hygiene and public health (Dr. H. T. Bulstrode), physiology (Dr. M. S. Pembrey), human anatomy and morphology (Mr. F. G. Parsons); (*e*) representatives nominated by the following boards of studies: preliminary medical studies—two (Professor F. Womack and Mr. J. A. Gardner); intermediate medical studies—two (Professor W. D. Halliburton and Mr. F. G. Parsons); advanced medical studies—four (Mr. Stanley Boyd, Dr. Sidney Phillips, Mr. S. G. Shattock, and Dr. H. Tilley); and (*f*) not more than six other members of the Faculty, to be appointed by the Faculty after nomination in each case by at least two members. The following members were proposed, seconded, and elected: Mr. Raymond Johnson, Mr. H. L. Eason, Dr. R. C. B. Wall, Dr. E. I. Spriggs, Dr. N. H. Alcock, and Dr. Louisa

B. Aldrich-Blake. It was resolved that the Senate be requested to publish the numbers of the successful candidates at the several examinations for medical degrees immediately after each meeting of the examiners. The election of two persons to represent the Faculty in the Senate for the period 1911–15 then took place. The following gentlemen had been proposed and seconded: Dr. W. P. Herringham, Mr. L. E. Hill, and Mr. H. J. Waring. The ballot resulted as follows: Mr. Hill 35 votes, Dr. Herringham 30 votes, and Mr. Waring 28 votes. Mr. Hill and Dr. Herringham were declared to have been elected. The meeting then terminated.

A PERMANENT MEDICAL EXHIBITION.—With the object of giving to medical men an opportunity of viewing the latest productions of pharmaceutical science and art, and incidentally of providing a central meeting place for medical men and their colleagues, Messrs. Burroughs, Wellcome, and Co. have opened a permanent exhibition at 54, Wigmore-street, London, W. A large room on the ground floor is fitted with a series of glass cases in which are displayed classified groups of "tabloid," "soloid," and other medicaments for use in the various departments of medicine and surgery, together with many ingenious compact cases for the pocket, for travelling, and for the consulting-room. Medicine chests, surgical dressings and instruments also receive attention. Vaccines and vaccine therapy are well exhibited in a large case, where are also shown specimens of the suprarenal capsule, thyroid gland, and pituitary body of man and other animals. To the display of diphtheria serum are added illustrations of the mode of preparation and so forth. In addition to the pharmaceutical products of the firm there is an exhibition of photographic chemicals and preparations for staining lantern slides. Various historical exhibits add to the merits of an instructive and entertaining exhibition, which is open from 9 A.M. till 6 P.M. on ordinary weekdays and from 9 A.M. till 1 P.M. on Saturdays. Journals and works of reference are available, and provision is made for medical men to write letters.

POOR-LAW MEDICAL OFFICERS' ASSOCIATION OF ENGLAND AND WALES.—A council meeting of this association was held at 34, Copthall-avenue, E.C., on March 16th, Mr. D. B. Balding presiding. The honorary secretary, Dr. Major Greenwood, and Mr. A. A. Napper reported that they had attended on behalf of the association the last meeting of the Poor-law Conference at Norfolk House, and that their recommendations *re* Poor-law medical reform had been adopted by that Conference with some slight modifications. Dr. Greenwood had also sent a copy of the same to the Local Government Board with a request that it might be laid before the departmental committee now sitting. Several letters were considered by the council from country members complaining of the addition to the work of the district medical officer without any extra remuneration caused by the recent Old Age Pension Acts. In many cases orders were given for attendance on old-age pensioners who in the past had been accustomed to pay a private medical practitioner. Before the passing of the Pension Acts the relatives had been willing to assist the pensioners, but now they held aloof, and the burden fell on the district medical officer. The chairman pointed out that it was illegal to place old-age pensioners on the permanent list of the district medical officer, and that a special order must be granted in each case. The council then considered the need of a closer communication between the executive of the association and the members generally throughout the country through the medium of a small periodical under its control, to be sent to all its members at regular intervals throughout the year.

THE MARYLEBONE HEALTH SOCIETY.—The annual meeting of this society was held in the council chamber of the town-hall, Marylebone, on March 20th, when the Mayor of Marylebone presided. In opening the proceedings the Mayor, after pointing out the splendid work which was done by the society in supplementing the work of the medical officer of health and the public health committee of the council, said he looked forward to the time, which would, he thought, be very short, when Marylebone, following Edinburgh, would reduce the death-rate from tuberculosis by 50 per cent. Dr. Charles Porter, the medical officer of health, in moving the adoption of the report, congratulated the society on the good work which it had done and made a strong appeal for more voluntary workers. He quoted the figures of the infantile death-rate since 1899, and showed that from that year, when the rate per 1000 births registered of deaths under one year of age was 191·5, there had been a steady decline to 98·9 in 1910. Dr. Eric Pritchard, who seconded the adoption of the report, hoped that the time would soon come when mothers would rear their children in a more intelligent manner. He would like to see less of the so-called maternal instinct and more of common-sense. The report was carried unanimously. The Rev. J. A. Beaumont and Miss Broadbent also addressed the meeting. Dr. Halliday Sutherland, in proposing a vote of thanks to the Mayor and council, spoke in terms of praise of the anti-tuberculous dispensary in connexion with the Health Society, remarking that they owed a deep debt of gratitude to Dr. Porter for the work which had been accomplished.

IRISH MEDICAL SCHOOLS AND GRADUATES' ASSOCIATION.—This association celebrated its St. Patrick's festival dinner on March 16th at the Hotel Cecil, Strand, London, when Sir Charles Cameron, the President, occupied the chair. The number of guests present was nearly 300, and included Sir Thomas Barlow, Sir James Dewar, Professor W. H. Thompson, Sir James Crichton-Browne, Mr. Henry Curtis, Dr. H. Macnaughton-Jones, Dr. M. J. Bulger, Mr. G. W. Dawson, Mr. T. Hobbs Crampton, Dr. William Douglas, and Mr. Campbell Boyd. The event of the evening was the presentation to Dr. Samuel Hamilton of the Arnott Memorial Medal. Dr. Hamilton was introduced by Mr. Crampton, who gave details of the great act of heroism performed by Dr. Hamilton at the Newport Dock disaster. Dr. Hamilton descended into a deep trench, the sides of which were caving in, and performed a surgical operation on a poor victim of the disaster who was pinned under some wreckage, finishing the operation as the tide rose in the trench. Dr. Macnaughton-Jones, in proposing the toast of "The Royal Colleges," made an eloquent speech for a grant in aid to the Royal College of Surgeons in Ireland, and Sir Thomas Barlow, in his reply to the toast, assured those present that the English Royal Colleges had every sympathy with such a movement. Dr. J. A. Macdonald, in submitting the toast of "Our Guests," made a graceful allusion to the presence of ladies at the dinner. Sir James Dewar, in replying to this toast, pointed out how pure science was indebted to Ireland. He interspersed his speech with many witty stories. The toast of "The Association" was entrusted to Sir James Crichton-Browne, who commenced by describing the gathering of that night as almost the most brilliant medical assembly he had attended in London. Sir Charles Cameron, in replying to the toast, made a capital after-dinner speech and gave an interesting account of the success and progress of the association. The evening concluded with a vote of thanks to the President, proposed by Professor Thompson.

DONATIONS AND BEQUESTS.—Under the will of the late Mrs. M. H. Christie the following bequests have been made: £4000 to the committee or association formed for the purpose of maintaining the David Lewis Manchester Epileptic Colony for the general purposes of the committee or association; £4000 to the Northern Counties Hospital for Incurables, as an endowment for the provision of five pensions of at least £20; £4000 to the Victoria Dental Hospital, Manchester; £4000 to the Manchester Northern Hospital for Women and Children; £4000 to the Christie Hospital, Manchester; £2000 to the Manchester and Salford Sick Poor and Private Nursing Institute; and £1000 to St. Mary's Hospital, Manchester. The testatrix also left £5000 to the Zenana Bible and Medical Mission for the erection of a hospital in India; £3200 to Epsom College (Royal Medical Foundation), as an endowment for the provision of two pensions of at least £40 each for medical men; and £500 to the Infants' Hospital in Vincent-square, Westminster.—The late Mr. W. Taylor of Eastbourne has by will, subject to the life interest of his wife, left £2000 to the Liverpool Royal Infirmary. £2000 to the Royal Hospital for Incurables, Putney; £2000 to the Hospital for Consumption and Diseases of the Chest, £2000 to the Cancer Hospital, £2000 to the Royal Free Hospital. £2000 to the Home for Confirmed Invalids, Highbury; £2000 to the North London Homes for Aged Christian Blind Men and Women, Hornsey Rise; and £1000 to the Samaritan Free Hospital for Women. He also

left £21,000 upon trust for certain relatives in each case for life, and subject thereto the money will be divided equally between the above-named hospitals. The Worshipful Company of Goldsmiths has sent £1000 to St. Bartholomew's Hospital towards the reduction of the building debt and £1000 to King's College Hospital, being the third donation of the Company towards the Removal Fund.

HAMPSTEAD PUBLIC MEDICAL SERVICE.—The second annual meeting will be held at 4.30 P.M. on Wednesday, March 29th, in the fencing studio of the Hampstead Conservatoire, Swiss Cottage. Anyone interested in the Public Medical Service movement is cordially invited to be present. The honorary secretary is Mr. A. R. Roche, M.R.C.S., &c., 99, Queen's-crescent, Haverstock Hill, N.W.

THE FLORENCE NIGHTINGALE MEMORIAL.—It has been decided by the joint committee chosen towards the end of last year that the memorial to Florence Nightingale shall consist of a statue to be erected in London, and an annuity fund for the relief of trained nurses who are destitute through inability to provide for old age or infirmity. A public meeting, under the presidency of the Lord Mayor, will be held at the Mansion House on March 31st in support of this proposal.

WORTHING CARE SOCIETY.—Proof of the good work that can be accomplished by a Children's Care Society comes from the borough of Worthing. For the ten years ended 1908 the infant mortality for the borough was 116 per 1000 births. In 1909, in only a part of which the society was working, the figure was brought down considerably, while for 1910 the mortality rate was only 66 per 1000. These figures are very encouraging, for they show what can be done when an organised campaign is taken up against the mortality amongst infants. Some time ago Worthing adopted the Notification of Births Act and also appointed a health visitor. It is further claimed for the society that the school attendance has increased from 87 to 92 per cent., thanks to the attention paid to the children in clothing and feeding.

MOSELEY HALL CONVALESCENT HOME FOR CHILDREN, BIRMINGHAM.—The nineteenth annual report stated that 857 children were admitted during the year compared with 976 in 1909. The average stay was 23 days. Of the 857 children admitted 450 were recommended by subscribers, 116 were transferred from the Children's Hospital, 291 from the General, Queen's, and other hospitals, the district nursing societies, dispensaries, &c. The income amounted to £2157, and the expenditure was £2387, leaving a deficiency of £230, compared with £212 in 1909. The average cost per head per week for maintenance was 3*s.* 6·8*d.*, compared with 3*s.* 7*d.* Mr. Tillyard, the organising secretary of the Charity Organisation Society, in proposing the election of officers at the annual meeting, said that the society was taking up the difficult question of following up the medical inspection of schools, and they thus came across a large number of delicate children and those recovering from illness. He pointed out the special need there was for dealing with consumptive children. Scarcely any sanatoriums admitted children, and it was not always desirable to mix children with adults. Moseley Hall was doing the work to a slight extent. If the committee possessed greater resources in the future he would like to suggest the provision of a wing or department for consumptive children. He also referred to the work of the open-air school, and pointed out that it could only be used by children who lived near the tramway serving the district. He asked whether it were possible to make arrangements for children to sleep at the home and attend the school in the day, so that the benefits of the school might be more evenly distributed over the city.

# Parliamentary Intelligence.

## NOTES ON CURRENT TOPICS.

### *Milk Legislation.*

SEVERAL important local authorities are promoting private Bills this session asking Parliament for powers to control the milk-supply of their respective areas. This fact has been brought to the notice of the President of the Local Government Board. Mr. BURNS has replied that he hopes that it may be possible to deal with the whole subject of milk-supply this session. Local authorities have received similar replies from Mr. BURNS in previous sessions, but his Bill, although introduced, failed to pass.

### *The Rag Flock Bill.*

The Rag Flock Bill, which has been introduced by Mr. BURNS, the President of the Local Government Board, in the House of Commons has been promptly printed. The purpose is "to prohibit the sale and use for the purpose of the manufacture of certain articles, of unclean flock manufactured from rags." There is only one operative clause. It reads as follows:—

It shall not be lawful for any person to sell or have in his possession for sale flock manufactured from rags or to use for the purpose of making any article of upholstery, cushions, or bedding flock manufactured from rags or to have in his possession flock manufactured from rags intended to be used for any such purpose, unless the flock conforms to such standard of cleanliness as may be prescribed by regulations to be made by the Local Government Board, and if any person sells or uses or has in his possession flock in contravention of this Act he shall be liable on summary conviction to a fine not exceeding, in the case of a first offence, *ten pounds*, or in the case of a second or subsequent offence *fifty pounds*.

Where in any proceedings against a person charged with an offence under this Act it is proved that an offence under this Act has been committed but that the person charged with the offence—(*a*) purchased the flock in respect of which the offence was committed from a person resident within the United Kingdom who sold the flock under a warranty that it complied with the prescribed standard of cleanliness; and (*b*) took reasonable steps to ascertain, and did in fact believe in, the accuracy of the statement contained in the warranty; the person so charged shall be entitled upon an information duly laid by him to have the person who gave the warranty brought before the court, and that person may be summarily convicted of the offence, and the person originally charged shall be exempt from any fine, and the person so convicted shall, in the discretion of the court, also be liable to pay any costs incidental to the proceedings.

Where a person is charged with having flock in his possession in contravention of this Act any flock proved in the proceedings to have been found in his possession shall be deemed to be intended for sale or for use in the manufacture of such articles as aforesaid, unless the contrary is proved.

It shall be the duty of a sanitary authority to enforce the provisions of this Act within their district, and for that purpose the medical officer of health, the inspector of nuisances or sanitary inspector, or any other officer whom the sanitary authority may appoint, shall have power, if so authorised by the sanitary authority, to institute and carry on any proceedings which the sanitary authority is authorised to institute and carry on under this Act, and to enter at all reasonable times any premises in which he has reasonable cause to believe that an offence under this Act is being committed, and to examine and take samples for the purposes of analysis of any flock found therein. Provided that where a sample is so taken the occupier may require the officer taking the sample to divide it into two parts and to mark, seal, and deliver to him one part. If any person wilfully obstructs any such officer in the execution of his powers under this section he shall be liable on summary conviction to a fine not exceeding *five pounds*.

The expenses of sanitary authorities under this Act shall be defrayed—(*a*) in the case of the Mayor, Aldermen, and Commons of the City of London in Common Council assembled, out of the general rate; (*b*) in the case of the council of a metropolitan borough, as part of the expenses incurred by the council in the execution of the Public Health (London) Act, 1891; (*c*) in the case of any other sanitary authority namely, the council of a municipal borough or urban or rural district, as part of the general expenses incurred in the execution of the Public Health Acts.

All fines imposed in any proceedings instituted by a sanitary authority in pursuance of their powers and duties under this Act shall be paid to the sanitary authority and carried to the credit of the fund out of which the expenses incurred by the authority under this Act are defrayed.

This Act shall apply to Scotland with the following modifications:—(*a*) The expression "Local Government Board" means the Local Government Board for Scotland; the expression "sanitary authority" means the local authority under the Public Health (Scotland) Act, 1897; and the expression "inspector of nuisances" means sanitary inspector. (*b*) The provision respecting the Rules Publication Act, 1893, shall have effect as if section one of that Act applied to Scotland with the substitution of the *Edinburgh Gazette* for the *London Gazette*. (*c*) The expenses of a local authority under this Act shall be defrayed out of the public health general assessment levied under the Public Health (Scotland) Act, 1897.

This Act shall apply to Ireland with the following modifications: (*a*) The Local Government Board for Ireland shall be substituted for the

Local Government Board; (*b*) the Public Health (Ireland) Acts, 1878 to 1907, shall be substituted for the Public Health Acts; and (*c*) the expression "medical officer of health" shall include a medical superintendent officer of health.

*Health Visitors Bill.*

The purpose of the Health Visitors Bill, which was introduced in the House of Commons on March 15th by Mr. BURNS, is to enable local authorities under the Notification of Births Act, 1907, to appoint health visitors. The Bill is a short one, the text of its principal clause running thus: "1. The local authority for the purposes of the Notification of Births Act, 1907, of any area outside London in which that Act is for the time being in force may appoint suitable women, to be known as health visitors, for the purpose of giving to persons advice as to the proper nurture, care, and management of children under five years of age, including the promotion of cleanliness. 2. The qualifications to be possessed by persons appointed to be health visitors under this section shall be such as the local authority may, after consultation with their medical officer of health, require."

*The Accounts of the General Medical Council.*

The accounts of the General Medical Council and the Branch Councils for the year 1910, and also of the Dental Registration Fund, have been presented to both Houses of Parliament.

## HOUSE OF COMMONS.

### WEDNESDAY, MARCH 15TH.

*Medical Practitioners and Rebates on Motor Spirit Duty.*

Mr. GINNELL asked the Secretary to the Treasury whether he was aware that rebate on motor spirit tax due to medical practitioners under the Finance (1909–1910) Act, 1910, was now paid in respect of the second financial year under that Act, but refused in respect of the first financial year under that Act, though the claims were supported by similar vouchers and proofs of actual payment; and whether he would say what further satisfaction the Commissioners of Customs and Excise required for the first year in addition to the class of documents that had satisfied them for the second. The honourable Member also asked, in view of the fact that the Finance (1909–1910) Act, 1910, entitles a medical practitioner to rebate of tax paid by him on petrol used in the practice of his profession, subject to no condition but proof of payment by him, by what authority did revenue officers withhold the rebate after all the requirements of the statute had been complied with; whether they had power to impose a condition not in the statute; whether, on their failure to collect tax due by other persons, they were entitled to withhold money due by them to the medical practitioner; and whether he would direct all rebate overdue to be paid forthwith.—Mr. HOBHOUSE replied: Under the provisions of the Finance (1909–10) Act a medical practitioner is not entitled to any rebate in respect of the duty on motor spirit used for supplying motive power to a motor-car kept for the purpose of his profession except on proof to the satisfaction of the Commissioners of Customs and Excise that the full duty has, in fact, been paid to the Crown on the spirit so used. The duty is not paid by the medical practitioner himself, nor by the dealer from whom he buys the spirit, but by the importer or manufacturer, and any voucher or certificate of payment of duty given by a dealer to a purchaser must be verified by the Customs and Excise authorities at the source at which the duty has been charged. Where claims for rebate can be so verified they are at once allowed, but the Commissioners of Customs and Excise cannot admit a claim where evidence that the duty has, in fact, been paid is not satisfactory. The practice of the Commissioners in dealing with claims for rebate is the same whether the claims relate to the year 1909–10 or 1910–11.

*Medical Inspection of School Children in the Highlands.*

Mr. WEIR asked the Lord Advocate whether, in view of the recommendations of the secondary education committees in Scotland in conjunction with the scheme for the medical inspection of school children, he would state the nature of the appointments which had been made in each of the Highland crofting counties.—Mr. URE answered: The following appointments have been made under the scheme for the medical inspection of school children:—*Inverness:* The county medical officer of health, Dr. J. Macdonald, has been appointed supervising medical officer, and Dr. Gordon Lang and Mr. Duncan Fletcher, school medical officers for the mainland and insular divisions respectively. Arrangements have also been made for obtaining the services of two nurses where required. *Ross and Cromarty:* The county medical officer of health, Dr. William Bruce, has been appointed supervising medical officer, and Dr. G. G. Middleton and Dr. Donald Murray, school medical officers for the mainland and insular divisions respectively. *Caithness and Sutherland:* The present medical officer of health for the two counties, Dr. G. Dick, is to be appointed joint medical officer of health and school medical officer for Caithness only. It is understood that a similar scheme is under consideration for Sutherland. No appointments have yet been made for Argyll, Orkney and Shetland, but a committee for the former county has been appointed to consider a scheme to come into force in the year 1911–12.

### THURSDAY, MARCH 16TH.

*Dentists and the Motor Spirit Duty.*

Mr. WILKIE asked the Secretary to the Treasury whether, in view of the fact that under the Finance Act of 1909–10 medical men using motor-cars in the discharge of their professional duties were remitted part of the licence duty on petrol, he would state whether this remission was also being deemed applicable to professional dentists using motor-cars in pursuit of their duties; and if not, would he state the reason for such differentiation of treatment?—Mr. HOBHOUSE replied: The relief allowed in respect of motor-car licence duty and motor spirit duty to duly qualified medical practitioners under the Finance (1909–10) Act, 1910, is not applicable to dentists using motor-cars. With regard to the latter part of the question I may point out that the saving of human life and suffering frequently depends upon a medical man possessing an expeditious means of locomotion, and in this respect the case of a dentist is not parallel.

*Small-pox and Vaccination.*

Mr. STAVELEY-HILL asked the President of the Local Government Board whether he would state what was the number of certificates of conscientious objection to vaccination received by the vaccination officers in respect of children whose births were registered during 1906, the number of statutory declarations of conscientious objection to vaccination received by the vaccination officers in respect of children whose births were registered during 1909, and the number, irrespective of the dates of the birth of the children whom they concerned in the years 1907 to 1910, respectively.—Mr. BURNS wrote in reply: The number of certificates of conscientious objection to vaccination received by the vaccination officers in respect of children whose births were registered during 1906 is 53,828. The number of certificates actually received in the years 1907–09 and in the first half of 1910, irrespective of the dates of the birth of the children, were—1907, 57,675; 1908, 162,799; 1909, 190,689; and 1910 (first half), 110,851. The other figures desired by the honourable Member are not yet available.

Mr. STAVELEY-HILL also asked the right honourable gentleman whether the official information in the hands of the Local Government Board showed that the spread of small-pox could be most effectively prevented by vaccination; whether it was the duty of boards of guardians, in whose areas the disease appeared, to take prompt measures, so far as the law allowed, to secure the vaccination or revaccination of all persons exposed to the danger of infection; and what action the Board was taking in view of the present outbreak.—Mr. BURNS furnished the following written reply: Small-pox is a contagious disease, and the most effective means of preventing its spread from the person attacked consists in removing the patient to a place of isolation and surrounding him by protected persons. Statistics relating to vaccination and small-pox obtained by my department are published, and I do not think it is necessary for me to attempt to interpret them. Boards of guardians are empowered by Section 28 of the Vaccination Act, 1867, to pay reasonable expenses incurred by them in taking measures to promote vaccination upon any actual or expected outbreak of small-pox. My officers have visited the districts in London recently affected by small-pox, and have conferred with the officials of the authorities as to the measures to be taken.

Mr. STAVELEY-HILL asked what were the areas in which cases of small-pox had been notified since January, 1911, and what was the number of such cases.—Mr. BURNS (by written answer) replied: The following list shows the counties in which cases of small-pox have been notified since January, 1911, and the number of cases notified in each: Cheshire, 8; Durham, 13; Essex, 2; Glamorgan, 1; Hertfordshire, 1; Lancashire, 26; London, 58; Middlesex, 1; Norfolk, 8; total, 118.

*The Remuneration of Vaccination Officers.*

Mr. STAVELEY-HILL asked the President of the Local Government Board whether he had at any time allowed boards of guardians to pay a fee to their vaccination officers for each statutory declaration of objection to vaccination received by them; and, if so, whether he would give the names of those boards of guardians and state whether their officers were still receiving such fees.—Mr. BURNS (by written answer) replied: The answer is in the negative.

Mr. STAVELEY-HILL also asked the right honourable gentleman whether boards of guardians had been advised that vaccination officers should receive gratuities in respect of the reduction in their income by the operation of the Vaccination Act, 1907; that such gratuities should be calculated on the difference in earnings at the present time and the average earnings during the years 1903–07; and that where the deficiency was likely to be permanent it was desirable to bring the officers' income to the former standard by increasing his fees; whether he had received any complaints and, if so, how many from vaccination officers to the effect that their boards of guardians had declined to follow this course; and what action he had taken in the matter.—Mr. BURNS wrote in reply: The Local Government Board has not taken any general action in regard to loss of income sustained by vaccination officers since the operation of the Vaccination Act, 1907. In many cases boards of guardians have awarded gratuities to their vaccination officers to meet the deficiencies in their incomes. The Board has sanctioned gratuities to meet the loss of income in the past, and has suggested to the guardians that where the deficiency was likely to be permanent the officers' fees should be increased. Many boards of guardians have adopted this suggestion, and the Board has sanctioned increased fees. In some cases vaccination officers have informed the Board of the loss they have sustained and that their guardians have not taken any steps to make up the deficiency. In these cases the Board has written to guardians setting out the average earnings of the vaccination officers in 1903–07 and the earnings since, and has suggested to the guardians that they should award gratuities based on the figures given and increase the officers' fees. Some boards of guardians have adopted the Board's suggestion, but others have declined to take any action. There are about 25 of the latter cases.

### MONDAY, MARCH 20TH.

*The Precedence of the Edinburgh Colleges.*

The Marquis of TULLIBARDINE asked the Lord Advocate under what authority the Secretary for Scotland recently advised or instructed the Lord Lyon King of Arms to refuse to decide a question of precedence between the Royal College of Surgeons and the Royal College of Physicians; and whether the Secretary for Scotland had any jurisdiction, direct or indirect, over the Lyon King of Arms as such.—Mr. URE replied: Questions of precedence are, in the view of the Secretary for Scotland, exclusively for the Sovereign to decide. The jurisdiction of the Lyon King at Arms is exclusively statutory and does not embrace questions of precedence. And the Lyon King, having invited an expression of opinion on the question referred to by the noble lord, received an answer upon the lines above indicated.

*The Supply of Antitoxin.*

Mr. CHANCELLOR asked the President of the Local Government Board whether he had seen the report of the medical officer of health of Islington in which he recommended that inoculation with antitoxin supplied free by the borough council should be commenced the moment diphtheria was suspected, and even before the diagnosis was positive; and what action he proposed to take to prevent local authorities from encouraging and subsidising this practice.—Mr. BURNS

answered: I have seen the report referred to, but I do not propose to interfere with the discretion of the local authorities in acting upon the provisions of the Order recently issued.

Mr. CHANCELLOR also asked the right honourable gentleman, when, seeing that Section 77 of the Public Health (London) Act, 1891, and Section 133 of the Public Health Act, 1875, under which the Local Government Board Order authorising local authorities to supply diphtheria antitoxin free, applied only to cases of a temporary nature, that Order would be withdrawn.—Mr. BURNS said in reply: The fact that the sections under which the Orders authorising the supply of antitoxin have been made refer to the provision of a temporary supply of medicine and medical assistance, does not, in my opinion, necessitate or render desirable the withdrawal of the Orders.

Mr. CHANCELLOR asked whether the right honourable gentleman was aware that, in addition to supplying antitoxin free, the Kensington borough council had offered every medical practitioner within the borough a fee of 5s. for every inoculation; how many other local authorities had adopted the same practice; whether such use of public money as a premium on a form of medical treatment whose value was disputed had been sanctioned by him; and, if so, under what statute.—Mr. BURNS answered: As regards the authority for the Orders issued by the Local Government Board in August last, empowering local authorities to provide diphtheria antitoxin, I may refer the honourable Member to an answer which I gave him in November last. By the terms of the Order the arrangements as to the keeping, distribution, and use of the antitoxin are required to be in accordance with the advice of the medical officer of health. I have no complete information as to the arrangements which have been made in Kensington or elsewhere.

*Vaccination in Stalybridge.*

Mr. SNOWDEN asked the President of the Local Government Board whether the town clerk of Stalybridge had sent a circular to all the medical men in his town offering a free supply of lymph for vaccinations; whether the Local Government Board had supplied him with this lymph; whether, in that case, his attention had been called to the fact that only public vaccinators might legally be supplied with it; whether the Stalybridge corporation was offering free revaccination; and, if so, whether he proposed to take any action in the matter.—Mr. BURNS said, in reply: The Local Government Board has not supplied lymph to the corporation of Stalybridge, but except as to this, I understand the facts are generally as stated in the question. No action on my part seems to be called for.

*Small-pox and Vaccination.*

Mr. SANDYS asked the President of the Local Government Board whether, in the opinion of the medical officers concerned, any of the circumstances or statistics relating to the recent outbreak of small-pox had thrown doubt upon the utility of vaccination as a preventive of that disease; and, if so, what was the nature of these circumstances or statistics.—Mr. BURNS answered: To the best of my knowledge the answer is in the negative.

TUESDAY, MARCH 21ST.

*Medical Inspection of School Children in London.*

Mr. WEDGWOOD asked the President of the Board of Education whether his attention had been called to Sir Victor Horsley's criticisms on the medical inspection of school children as carried out by the London County Council; whether he would inquire into the justification for these criticisms; and, if warranted, whether he could take any steps to induce the London County Council to remedy the existing state of affairs.—Mr. RUNCIMAN replied: I have seen a newspaper report of the recent speech of Sir Victor Horsley on this subject. I have a great respect for this distinguished surgeon's opinion upon subjects on which he speaks with special authority, but I am not sure that the organisation of the medical inspection of school children is one of them. The Board is cognisant of the circumstances of medical inspection in London, and has recently made a communication to the London County Council on that matter.

WEDNESDAY, MARCH 22ND.

*Epidemic at Osborne.*

Major GASTRELL asked the First Lord of the Admiralty how many boys at Osborne College during the present term had suffered from measles, German measles, and pink-eye respectively.—Mr. MCKENNA replied: A hundred and fifteen cadets have had measles, 258 have had German measles, and there have been 60 cases of conjunctivitis, popularly miscalled pink-eye, but many of them were only slight and in association with attacks of measles. In the opinion of the Admiralty the existing medical staff is qualified to detect the first symptoms of disease.

Major GASTRELL further asked whether medical opinion attributed the prevalence of the illness known as pink-eye at Osborne College to the fact that part of the college was built upon the site of the stables formerly attached to Osborne House; and whether steps would be taken to remedy the existing conditions.—Mr. MCKENNA said in reply: Conjunctivitis, the disease sometimes miscalled pink-eye, cannot be said to be prevalent at Osborne. There was an outbreak of it in 1904 and it was considered by the medical authorities to be microbic in character, the organisms being spread by contagion and not air-borne. There have been a few sporadic cases since, and during the present term there have been, as I have just stated, a number of slight cases mostly in association with the current epidemic of measles. I would add that pink-eye, being an equine disease, has no known connexion with the conjunctivitis to which the cadets at Osborne have been subject.

## BOOKS, ETC., RECEIVED.

RIDDELL.—On March 16th, at Highgate, Kendal, the wife of David Riddell, M.D., a son.
STUBBS.—On March 7th, at Highfield, Tulse Hill, S.W., the wife of John D. Stubbs, M.B., B.C. Cantab., of a son.

## DEATHS.

PALEY.—On March 13th, at Heathfield Lodge, Ealing, William Paley, M.D., formerly of Peterborough, in his 95th year.

*N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

# Notes, Short Comments, and Answers to Correspondents.

## MEDICAL FOLK-LORE IN NORWAY.

THROUGH a circular in the *Norsk Skoletidende* of March 4th an interesting attempt has been made to enlist the help of the teachers of Norway in collecting materials for an account of medical folk-lore in that country. A list is first given of about 60 ailments, epidemic complaints, internal complaints, diseases of hair, skin, or nails; and opposite the scientific name are to be put the various popular names in the dialects. In a second division any popular remedies drawn from the animal, vegetable, or mineral kingdoms are to be noted, also any peculiar methods of a surgical character used by midwife, dentist, barber, or the like. Particulars are also asked for with regard to alleged cures by superstitious means, such as spells, incantations, amulets, or wells of healing; and the names, or at least the initials, are to be given of herbalists, quacks, "wise women," who in present or in past times have played a part in their respective neighbourhoods. The particulars are to be sent in to two physicians, Dr. F. G. Gade and Dr. Grön of Christiania, who receive a grant from the Nansen Fund for the expenses of the inquiry.

## THE HANDLING OF HOT SUBSTANCES BY ORIENTALS.

*To the Editor of* THE LANCET.

SIR,—The article in THE LANCET of March 18th regarding "An Egyptian Holy Man" casts doubt on the feats of holding a hot iron bar between the teeth and of handling red-hot embers without incurring a lesion of the skin. May I draw your attention to the following fact within my experience?

When living in camp with some of Professor Flinders Petrie's workers from Quft (Qift) it was quite usual to see the cook-boy Ibrahim Abd El Kerim, dipping his hand into boiling oil while frying an omelette. We used to watch him deliberately pass his hand under the omelette, fold it over, and afterwards lift it out on to a dish.

This is a peculiarity of handling hot substances which comes to the European as a surprise, but which to the Arab seems a matter of course.

I am, Sir, yours faithfully,

South Hampstead, March 20th, 1911. LINA ECKENSTEIN.

## THE CHILD EMIGRATION SOCIETY.

THIS society, which was founded in 1909 as a result of a paper read at the Colonial Club, Oxford, by Mr. Kingsley Fairbridge of Rhodesia, a Rhodes scholar, of Exeter College, held its first annual meeting last year, at which definite rules were adopted for the conduct of the society's operations, and an executive committee was elected. The balance sheet showed that £650 had been raised. The basis of its action is the conviction that no permanent solution of any of our great social questions—pauperism, crime, imbecility, sickness, unemployment, &c.—is possible until we are prepared to guarantee a fair start in life to the thousands of underfed and ill-treated children in the land. The effect of existing rescue and training societies is to throw their protégés into an overcrowded labour market to compete with the children of self-supporting workmen on terms disadvantageous to the latter. This would be obviated by following Mr. Fairbridge's suggestion to transfer the training ground of many of these children to the overseas dominions and to fit them to compete in a market where the demand for efficient British labour is always greater than the supply. Mr. Cuthbert W. H. Whalley, Claddagh, Woodstock-road, Oxford, who has received from the society a roving commission as organising secretary, sends us an appeal asking for donations, subscriptions, meetings, voluntary workers, and speakers to coöperate in the work of opening in 1912 such an experimental school, either in Newfoundland, where a free grant of land has been offered by the Government, or wherever else a grant of suitable land can be secured.

## ELECTRO-MEDICAL APPARATUS.

A VERY instructive and complete catalogue of electro-medical apparatus has recently been issued by Messrs. Newton and Co., of 3, Fleet-street, Temple Bar, London. Considerable space is devoted in the introductory chapters to the explanation of the principles and practice of electrical methods. It is an undoubted fact that there are still a good many medical practitioners who have not concerned themselves seriously to give electricity a systematic study or to understand the many terms used in regard to its applications. Information on such points is here given, which should be of distinct assistance to the beginner in such a study. Besides, there are a great number of illustrations of the various apparatus employed in electro-therapeutics made by this firm. We note that amongst other recent introductions the Dessauer "one-flash" X ray apparatus is described. With this apparatus the exposure is not measured by seconds, but consists of one single discharge only. This gives the unquestionable advantage that every organ of the body can be photographed with all movement eliminated.

### THE WARD PIN-CUSHION.

THIS consists of an improved metal case for the reception of safety-pins and a cushion for ordinary pins. The advantages claimed for it are: (1) The safety-pins are enclosed in the case, easy to extract, and free from any encumbrance; (2) the ordinary pins are pressed in a pad of wool which can be removed, destroyed, and replaced by sterilised wool; and (3) the case (with pins) complete can be sterilised by boiling. The case is made in aluminium in the shape of a cross, and will hold one dozen safety-pins from 1 in. to 2½ in. It can be attached to the apron by either safety-pin or chain. The inventor is Mr. J. Hayward, 63, Francis-street West, Hull.

*R. H.*—We do not know the stove in question. The whole subject has been taken by our correspondent into a very technical region. We suggest that he should get "Gas Fires and Chimney Flues," by E. W. Browning, Office of *Journal of Gas Lighting*, and "Model Heating," the catalogue of the Gas Light and Coke Company, Horseferry-road, S.W., where he will find the views held by THE LANCET set out and largely endorsed. We will try to obtain for our correspondent exact answers to his questions.

*D. M. M.*—We are unable to find the reference. We know of no such use of a rubber ball, but there does not seem to be any reason why a rubber ball should not be used in place of the usual boxwood one.

**COMMUNICATIONS not noticed in our present issue will receive attention in our next.**

### A DIARY OF CONGRESSES.

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced for March, and April, 1911:—

March 28th–April 25th (Tunis).—Exhibition of Hygiene.
April 4th–7th (London).—Fourth Annual Nursing and Midwifery Conference and Exhibition.
,, 18th–20th (Paris).—Third Congress of Physiotherapy of French-speaking Physicians.
,, 18th (Berlin).—Tenth Congress of the German Orthopædic Surgery Society.
,, 19th–22nd (Berlin).—German Surgical Congress. (Fortieth Annual Meeting.)
,, 19th–22nd (Wiesbaden).—Twenty-eighth German Congress of Internal Medicine.
,, 20th–22nd (Groningen).—Thirteenth Nature and Medical Congress.

## METEOROLOGICAL READINGS.

**The following journals, magazines, &c., have been received:—**
Classical Review, Birmingham Medical Review, Bulletin of the Johns Hopkins Hospital, Maryland Medical Journal, American Journal of Obstetrics, Journal of Tropical Medicine and Hygiene, Pacific Medical Journal, Ash's Monthly, South African Medical Record, Century Illustrated Monthly Magazine, Bulletin de l'Association Française pour l'Étude du Cancer, La Revue du Cancer, St. Louis Medical Review, American Journal of Surgery, Sleeping Sickness Bureau Bulletin, Clinique Ophtalmologique, Indian Public Health, Symons's Meteorological Magazine, British Journal of Dental Science, Revista Dental, Archivos Españoles de Neurologia, Psyquiatria y Fisioterapia, Revista Stiintelor Medicale, Malaya Medical Journal, Hospital Assistant, Indian Medical Record, The Therapist, American Journal of Clinical Medicine, Jahrbuch für Kinderheilkunde, Medical Chronicle, Albany Medical Annals, Recueil d'Ophtalmologie, American Medicine, Interstate Medical Journal, Bulletin of the Office International d'Hygiène Publique, Transactions of the Ophthalmological Society of the United Kingdom, Bristol Medico-Chirurgical Journal, Journal of Pathology and Bacteriology.

# Medical Diary for the ensuing Week.

## SOCIETIES.

**ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W. (temporary address during building of new house).**

MONDAY.
ODONTOLOGICAL SECTION (Hon. Secretaries—E. B. Dowsett, W. W. James): at 8 P.M.
*Paper:*
Mr. H. J. Morris and Professor McWilliam: The Comparative Elasticity and Internal Structure of Cast and Rolled Gold Plate.
*Casual Communication:*
Mr. Howard Mummery: A Short Preliminary Note on the Distribution of the Nerves of the Dental Pulp.

TUESDAY.
MEDICAL SECTION (Hon. Secretaries—A. F. Voelcker, Sir John F. H. Broadbent, Bt.): at 5.30 P.M.
*Papers:*
Dr. Thomas Lewis: Electro-cardiograms.
Dr. Samuel West: Cases of Suffocative Catarrh in the Adult (Acute Pneumococcal Bronchitis).

**MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.**

MONDAY.—8.30 P.M., Clinical Evening. Cases will be exhibited by Dr. E. Wynter, Dr. Langmead, Mr. W. Trotter, Mr. W. H. Battle, Dr. StClair Thomson, and others. Patients will be in attendance at 8 P.M.

**HARVEIAN SOCIETY OF LONDON, Stafford Rooms, Titchborne-street, Edgware-road, W.**

THURSDAY.—8.30 P.M., Mr. C. B. Lockwood: Fractures of the Patella and their Surgical Treatment. (Harveian Lecture.)

## LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

**ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East.**

TUESDAY AND THURSDAY.—5 P.M., Dr. J. M. Bruce: Clinical Study of Cardio-vascular Regeneration (Lumleian Lectures).

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.**

MONDAY.—4 P.M., Mr. W. Evans: Clinique (Skin). 5.15 P.M., Lecture:—Mr. A. Lane: Intestinal Stasis.
TUESDAY.—4 P.M., Dr. W. Hunter: Clinique (Medical). 5.15 P.M., Lecture:—Dr. A. F. Tredgold: The Borderland of Insanity.
WEDNESDAY.—4 P.M., Mr. J. T. Walker: Clinique (Surgical). 5.15 P.M., Lecture:—Mr. H. Fisher: Some Cases of Lesions of the Optic Chiasma.
THURSDAY.—4 P.M., Mr. P. J. Freyer: Clinique (Surgical). 5.15 P.M., Lecture:—Mr. A. H. Tubby: Treatment of Scoliosis in Childhood and Adolescence.
FRIDAY.—4 P.M., Dr. D. McKenzie: Clinique (Ear, Nose, and Throat).

**POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.**

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye.
TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin.
WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M., Dr. Simson: Diseases of Women.
THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye.
FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin.
SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

**NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.**

MONDAY.—Clinics:—10 A.M., Surgical Out-patient (Mr. E. Gillespie), 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Nose, Throat, and Ear (Mr. H. W. Carson).
TUESDAY.—Clinic:—10 A.M., Medical Out-patient (Dr. A. G. Auld). 2.30 P.M., Operations. Clinics:—Surgical (Mr. Howell Evans); Gynæcological (Dr. A. E. Giles). 3.30 P.M., Medical In-patient: (Dr. A. J. Whiting).
WEDNESDAY.—Clinics:—2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks). 3 P.M., X Rays (Dr. A. H. Pirie).
THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson). 3 P.M., Medical In-patient (Dr. G. P. Chappel).
FRIDAY.—2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld); Surgical (Mr. E. Gillespie); Eye (Mr. R. P. Brooks). 3 P.M., Medical In-patient (Dr. R. M. Leslie).]

## EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is frequently necessary that attention should be given to this notice.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.*

*Lectures, original articles, and reports should be written on one side of the paper only,* AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale and advertising departments of* THE LANCET *should be addressed "To the Manager."*

*We cannot undertake to return MSS. not used.*

## MANAGER'S NOTICES.

### THE INDEX TO THE LANCET.

The Index and Title-page to Vol. II. of 1910 were given in THE LANCET of Dec. 31st, 1910.

### VOLUMES AND CASES.

VOLUMES for the second half of the year 1910 are now ready. Bound in cloth, gilt lettered, price 16*s.*, carriage extra.

Cases for binding the half-year's numbers are now ready. Cloth, gilt lettered, price 2*s.*, by post 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

### TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

| FOR THE UNITED KINGDOM. | | TO THE COLONIES AND ABROAD. | |
|---|---|---|---|
| One Year ... ... ... | £1 1 0 | One Year ... ... ... | £1 5 0 |
| Six Months ... ... ... | 0 12 6 | Six Months ... ... ... | 0 14 0 |
| Three Months ... ... | 0 6 6 | Three Months ... ... | 0 7 0 |

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rate of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

### TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at these rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.
